BUSINESS MANAGER

J. R. BRUCE

Copyrighted 1949, by the
Minnesota State Medical Association

"Therefore, more than in any other disease, it is necessary in the treatment of an individual patient with syphilis to follow a therapeutic regimen which, after *long-term study* in *large series of patients,* has been established as *satisfactory* for the particular type of syphilis under consideration."*

an arsenical of choice in the treatment of syphilis

long-term study

more than a decade of clinical evaluation.

large series of patients

over two hundred million injections already administered.

satisfactory

high therapeutic effectiveness with notable safety in causing disappearance of spirochetes, healing of lesions and reversal of seropositivity in a large percentage of cases.

MAPHARSEN (oxophenarsine hydrochloride, P. D. & Co.) is supplied in single dose ampoules of 0.04 Gm. and 0.06 Gm., boxes of 10, and in multiple dose ampoules of 0.6 Gm. in boxes of 10.

*Cecil, R. A.: A Textbook of Medicine. Philadelphia, W. B. Saunders Co., 1947, p. 376.

Look at Your Income This Way

You can't lock it up in a vault to protect it. Yet it is more important than any personal property that you may own, and if anything should happen to it, you would stand to lose plenty.

It is logical that this plan of your Association, using its buying power, can do more for you than any individually purchased policy. Mute testimony for that point is the many professional organizations that have investigated and tested this special plan of disability insurance.

You can't eat accident and sickness insurance, but it will certainly keep you from starving.

DELAY offers no advantage—CALL US NOW!

from Einthoven* to ERA...

*WILHELM F. EINTHOVEN—Physicist, inventor of the quartz string electrocardiograph and Nobel Prize winner for his pioneer work in cardiography.

The standard of accuracy in cardiography has always been the quartz string galvanometer electrocardiograph. Cardiograms taken on quartz string electrocardiographs were used by the pioneers in cardiology to establish the cardiographic normals and abnormals used today. The compact, portable BECK-LEE electrocardiograph of today represents a tremendous improvement over the gigantic, fixed instrument first used by Einthoven, but the basic source of their proven accuracy remains the same—a true quartz string galvanometer.

BECK-LEE, originators of the permanent magnet quartz string galvanometer, automatic compensation and now—the Record Automatic Camera.

Write for our BECK-LEE Electrocardiograph Catalog MM-149

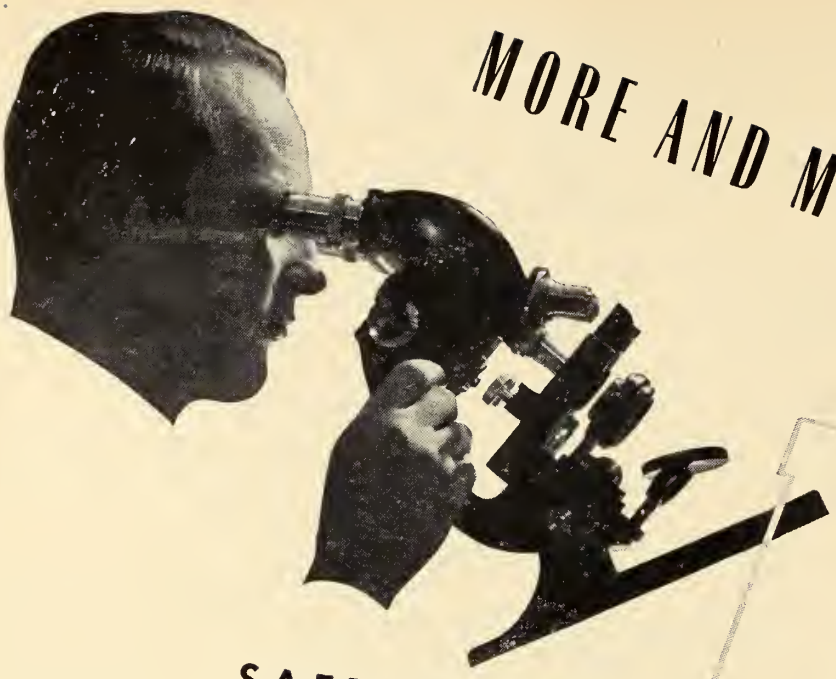
WITH MAY-O-LITE . . .

you never have eyes in the back of your head!

Recently a Minnesotan who works in a large manufacturing plant complained of eye strain. His office desk was arranged so that the windows were at his back, thereby eliminating the extreme light from the southern exposure. However, venetian blinds on the windows reflected in his glasses. Not only was it a strain upon his eyes, but it was bothersome. Quite often he even found himself counting the slats of the blinds. It was as if he had eyes in the back of his head.



The next time his glasses were changed, he had them coated with MAY-O-LITE. Today, he says, "I don't have any more slat trouble."

When objects behind you reflect in your glasses it causes additional eye strain, tends to make you nervous and irritable.

MAY-O-LITE is a scientific method of cutting down annoying surface reflections on your glasses. With MAY-O-LITE, the reflections are reduced from 80 to 95%, eye strain is minimized and lenses become far more resistant to scratches.

MAY-O-LITE Low Reflection Lens Coating is available through your manufacturing and dispensing optician. Write for a descriptive pamphlet and a treated sample of glass, today.

DIHYDROSTREPTOMYCIN

A New, Dramatic Advance In Antibiotic Therapy

- Extremely Low Incidence of Vestibular Disturbances
- Less Frequent Allergic Manifestations
- Unsurpassed Purity
- Undiminished Antibacterial Activity against *Mycobacterium tuberculosis*

Dihydrostreptomycin Merck is a new, highly purified antibiotic, chemically distinct from streptomycin, and characterized by greatly reduced neurotoxicity.

Allergic manifestations due to dihydrostreptomycin therapy are rare, and no local skin irritation or other allergic phenomena have been reported thus far among personnel who frequently handle this drug.

Dihydrostreptomycin Merck and Streptomycin Calcium Chloride Complex Merck may be used interchangeably in the treatment of tuberculosis.

DIHYDROSTREPTOMYCIN MERCK

The Importance of Protein Adequacy In Diabetes Mellitus

It appears in the light of recent experience that the daily protein requirement of the diabetic has been underestimated and calls for an upward revision.

The success obtained in diabetic retinopathy from the use of high protein diets emphasizes the deleterious possibilities of hypoalbuminemia in this metabolic disease.

In view of the excellent results observed from a high protein intake, in many forms of hepatic disease, a dietary rich in protein is suggested as a therapeutic measure in the management of liver enlargement, one of the frequent complications of diabetes.[1] Since impaired liver function reduces the efficacy of insulin, prevention of liver enlargement by a liberal allowance of protein in the daily diet of the diabetic appears an important factor in the control of this disease. With an estimated 2,000,000 diabetics in the United States[2] every benefit achieved in this field makes itself felt on a truly large scale.

Meat is an outstanding source of protein in the dietary of the patient with diabetes mellitus for these reasons: It is notably rich in protein, from 17 to 20 per cent of its uncooked, and from 25 to 30 per cent of its cooked weight. The protein of meat, regardless of cut or kind, whether fresh, cured, or canned, is biologically complete. All meat is of excellent digestibility—from 96 to 98 per cent. Furthermore, meat ranks with the best sources of B vitamins, potassium and phosphorus, all of which are essential factors in the metabolism of carbohydrate.

by far the most potent ORAL ESTROGEN available clinically

In exceedingly minute doses—as little as 0.02 mg. (1/3200 gr.) daily—ESTINYL* maintains the average menopausal patient free of symptoms. Even when initiating therapy and in the more severe cases, unusually small dosage—measured in hundredths of a milligram—has been found effective.

ESTINYL

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

(ETHINYL ESTRADIOL)

ESTINYL, a derivative of the ovarian follicular hormone, estradiol, evokes the sense of well-being characteristic of natural hormone therapy. It acts rapidly, often completely controlling climacteric symptoms within a few days. In therapeutic dosage side effects are notably infrequent. Unique response to minimal dosage permits effective estrogen therapy at low cost to patients.

DOSAGE: One ESTINYL Tablet (0.02 mg.) or one teaspoonful of ESTINYL LIQUID (0.03 mg.) daily, may be prescribed, reducing dosage as symptoms subside.

ESTINYL Tablets, 0.02 (buff) or 0.05 mg. (pink), in bottles of 100, 250 and 1000.

ESTINYL LIQUID, 0.03 mg. per 4 cc. (teaspoonful), in bottles of 4 and 16 oz.

Clinically approved

Today, there is a wealth of clinical evidence supporting the use of Meonine as a supplement to the protein-rich diet usually prescribed for liver damage associated with malnutrition, pregnancy, allergy, certain chemical poisons, and alcoholism.

Typical of this evidence is a Beams-Endicott paper*. The authors reported that a methionine supplement seemed to cause regeneration of the liver parenchyma, in cirrhotic patients, irrespective of the amount of protein and vitamins in the diet.

Complete bibliography on request. Meonine is supplied in 0.5 gram tablets. Wyeth, Philadelphia, Pa.

4 Pertinent Questions for Busy Doctors

Do you have the time and all the facilities you need to:

1. Watch ever-changing economic and business trends?
2. Study the position of various industries in a swiftly-changing world?
3. Analyze the relative standing of key corporations within leading industries?
4. Judge the net effect of the countless factors tending to alter the value of the securities you own?

Many physicians and other professional men and women, as well as business executives, societies, trusts and corporations employ us to attend to these activities—so necessary for the long-term conservation of property.

We shall be pleased to discuss your investment situation and the ways we can be of assistance to you, at your convenience. No obligation.

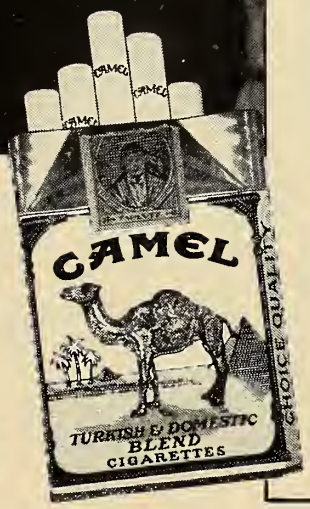
PROVE CAMEL MILDNESS *for Yourself!*



R. J. Reynolds Tobacco Co., Winston-Salem, N. C.

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS THAN ANY OTHER CIGARETTE

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel!

Test for yourself what throat specialists reported when a 30-day smoking test revealed:

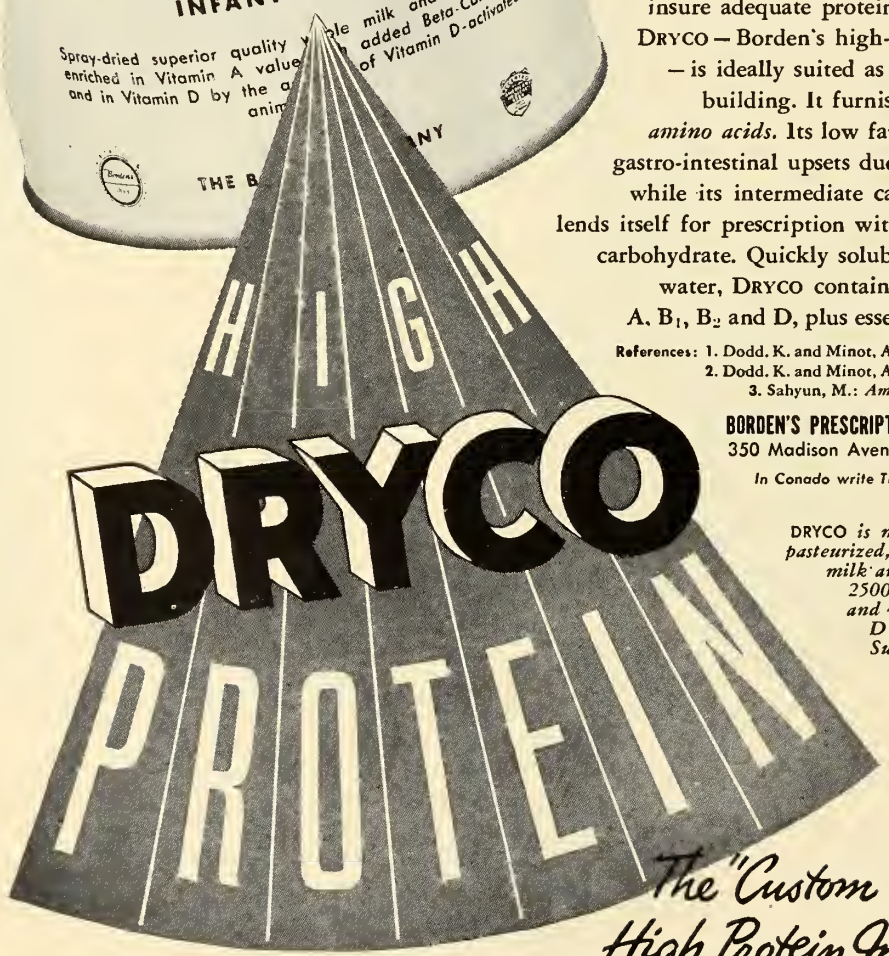
"NO THROAT IRRITATION due to smoking CAMELS!"

MAKE YOUR OWN 30-DAY CAMEL MILDNESS TEST. Smoke Camels, and only Camels, for 30 days. Prove for yourself how mild Camels *are!*

Hundreds of men and women, from coast to coast, recently made a similar test. They smoked an average of one to two packs of Camels a day for 30 days. Their throats were carefully examined by throat specialists. And after a total of 2470 examinations—these throat specialists reported *"not one single case of throat irritation due to smoking Camels!"*

But prove it yourself... in your "T-Zone" (T for Taste and T for Throat). Let YOUR OWN TASTE tell you about the rich, full flavor of Camel's choice tobaccos. Let YOUR OWN THROAT give the good news of Camel's cool, cool mildness.

THE HIGH-PROTEIN INFANT FOOD



The incidence of mild protein deficiencies in children, predisposing toward infections and edema, is reported[1,2] much greater than generally realized. Infant and adolescent requirements—not only for tissue repair and maintenance, but also for growth—are much higher than in adulthood.[3] To insure adequate protein intake in infancy, DRYCO—Borden's high-protein infant food—is ideally suited as a basis for formula building. It furnishes *all the essential amino acids.* Its low fat content minimizes gastro-intestinal upsets due to fat intolerance, while its intermediate carbohydrate content lends itself for prescription with or without added carbohydrate. Quickly soluble in cold or warm water, DRYCO contains adequate vitamins A, B_1, B_2 and D, plus essential milk minerals.

DRYCO *is made from spray-dried, pasteurized, superior quality whole milk and skim milk. Provides 2500 U.S.P. units vitamin A and 400 U.S.P. units vitamin D per reconstituted quart. Supplies 31½ calories per tablespoon. Available at all drug stores in 1 and 2½ lb. cans.*

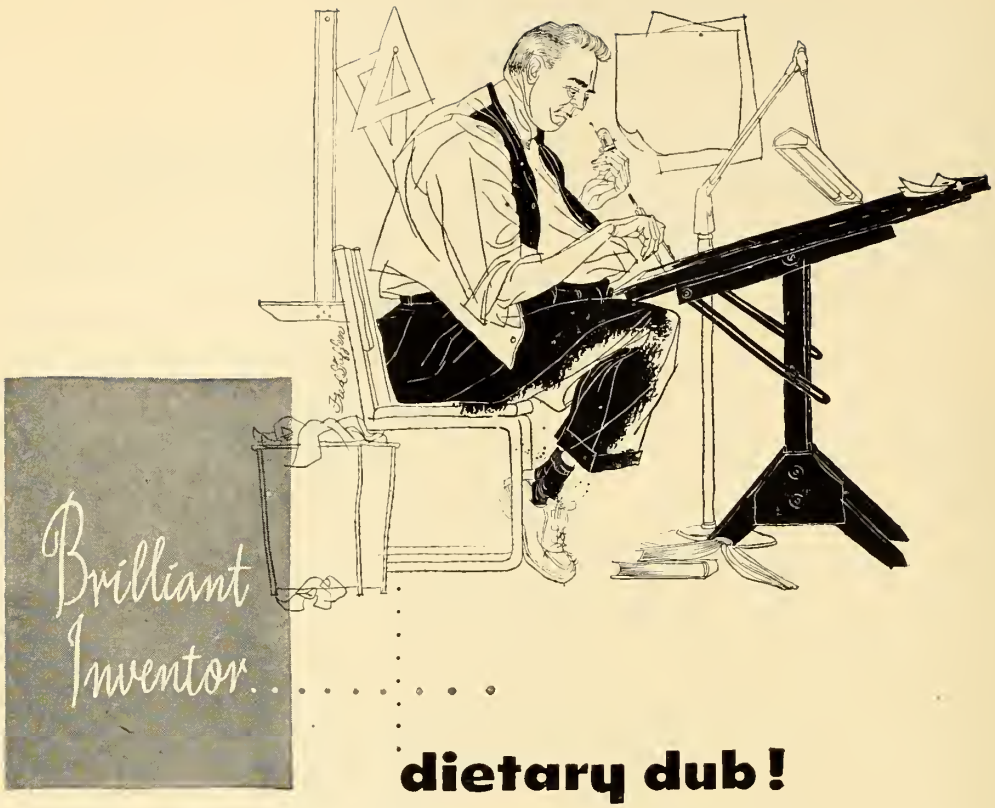
The "Custom Formula" High Protein Infant Food

℞: only 2 or 3 drops

PRIVINE 0.05%

a distinguished nasal vasoconstrictor

HIGHLY POTENT: Prompt, complete relief from nasal congestion and hypersecretion usually results from only 2 or 3 drops of Privine hydrochloride 0.05%. Each application provides 2 to 6 hours of nasal comfort.



BLAND, NON-IRRITATING: Privine is prepared in an isotonic aqueous solution buffered to a pH of 6.2 to 6.3. Artificial differences in osmotic pressure between solution and epithelium are avoided. Thus, stinging and burning usually are absent.

Privine is generally free of systemic effect. The occasional sedative effect that may be noted in infants and young children is usually due to gross overdosage. Since there is virtually no central nervous stimulation, Privine may be applied before retiring with no resultant interference with restful sleep.

PRIVINE: 0.05% in 1-ounce dropper bottles and 1-pint bottles; 0.1% strength reserved for office procedures, in 1-pint bottles only.

dietary dub!

Factories throb to the pound of his inventions—while he sits. Hour after silent hour he sits and schemes mechanical schemes or times the pace of tiny models. In his spare time? Moves to a rocking chair and reads. Has no appetite? Neither do hundreds of others whose occupations or pastimes require little physical energy. And you could cite many other reasons for inadequate diets—excessive smoking, indifference, ignorance, strong likes and dislikes . . . In many such cases, your prescription for one or more vitamins accompanies your advice on dietary reform. When you prescribe an Abbott product, you are assured that your patient will receive the full potencies intended. There is an Abbott vitamin product to fill every need—for one or a combination of vitamins, for supplementary or therapeutic levels of dosage, for oral or parenteral administration. Your pharmacy will be glad to fill your prescriptions.

"SMOKE LESS...OR CHANGE TO PHILIP MORRIS"

... if smokers are affected by the irritant properties of cigarette smoke

Sometimes physicians may advise "Don't smoke at all." But even where that is indicated, how many patients will forego the pleasure of smoking?

For such patients, as for *all* smokers, the choice should be the least irritating of cigarettes. Many throat specialists suggest Philip Morris* because they are convinced from published studies**, *as well as their own observations* that Philip Morris alone, of all the leading cigarettes, is by far the least irritating to the sensitive tissues of the nose and throat.

Perhaps you too will find it advisable to suggest to your patients who smoke . . ."Change to Philip Morris."

PHILIP MORRIS

Philip Morris & Co., Ltd., Inc., 119 Fifth Avenue, N. Y.

IF YOU SMOKE A PIPE...We suggest an unusually fine new blend—COUNTRY DOCTOR PIPE MIXTURE. Made by the same process as used in the manufacture of Philip Morris Cigarettes.

CAMP SUPPORTS *for the* LOW BACK

Discussing the general treatment of low back pain in a recent article, an orthopedic surgeon* comments on supports (among other items) as follows: "The second remedy tried by time is further rest provided by support after the patient gets out of bed. Various corsets, braces, and casts have been used and the one criterion is that they be well fitted and do the work intended."

For the Intermediate-to-Stocky Type of Build

The Camp lumbosacral support (illustrated) fits down over the gluteal region and restricts the motion of the pelvic and lumbar joints. The lower adjustment following about the major portion of the pelvic girdle is a prime factor in relieving the weight-bearing joints of the lower spine.

The support lends itself readily to reinforcement with the Camp spinal brace (illustrated). The brace is made of spring steel and comes in varying lengths — twelve, fourteen, sixteen, and eighteen inch lengths. Aluminum uprights and pads are also provided by Camp for reinforcement of orthopedic supports.

Camp fitters are trained and supervised by nurses and instructors.

These 'picture-words' represent a primitive classification of urines used by early Babylonian and Egyptian physicians.

centuries to perfect seconds to perform

When Sumerian and Babylonian physicians, *circa* 4000 B.C., noted the varying colors and constitutions of the "water of the phallus," they were probably not the first uroscopists in history. They were assuredly not the last, for fifty-odd centuries were to elapse before Fehling's first paper on the copper reduction test for urine-sugar appeared in 1848.

But centuries to perfect diagnostic procedures are condensed into seconds to perform the reliable *Clinitest*® method for urine-sugar levels. From start to finish, the test takes less than a minute. This tablet method is simplicity itself . . . readily learned by every diabetic patient. External heating is uniquely eliminated by the *Clinitest* procedure. Routine test interpretation is made easy.

RESEARCH M&R NUTRITION SERVICE

No milk laboratory in the world more modern!

This is the new three and one-half million dollar Sturgis (Michigan) Similac Laboratory. This additional capacity was made necessary by your confidence in Similac, and your increasing use of the product in your infant feeding practice.

The years of basic and clinical research which preceded the introduction of Similac, established with us a *habit* for research. And the many years of acceptance which Similac has enjoyed *since* its introduction, make us fully conscious that continuing research is an obligation.

In our present resources to fulfill this obligation we take a pardonable pride.

But our *greatest* pride will continue to be the high esteem in which Similac is held by Doctors everywhere.

THE ROLE OF X-RAY PELVIMETRY IN OBSTETRICS

PAUL C. HODGES, M.D.
Chicago, Illinois

MOST American radiologists of my vintage knew Russell D. Carman personally, but through quirks of circumstance I was denied that pleasure. When I first visited the x-ray department at the Mayo Clinic in the winter of 1911-12, Carman had not yet come, and by the time I worked as a student assistant to Walter Mills in St. Louis in 1916, Carman had left that city and his association with Mills to go to Rochester. Following the first World War, my home was outside the country for seven years, and in 1926, before I returned to the United States, Carman died of the very disease that had been his special field of study.

Like radiologists everywhere, I have been influenced strongly by the work of this great exponent of our profession, and I am honored indeed to be invited to give one of the lectures in this series that was created to do honor to his memory.

Pelvimetry

X-rays have been available to physicians for more than half a century and, of course, geometry is some twenty-two centuries old; but though x-ray pelvimetry requires only simple geometry applied to quite ordinary looking pelvic roentegenograms, it has not yet come to occupy a place of much importance in obstetrics. To some extent, radiology is to blame for this fact, but according to Nicholson Eastman, who is chairman of the Department of Obstetrics at Johns Hopkins University, most of the blame attaches to the fact that obstetricians have been slow to accept pelvimetry of any sort and not sufficiently critical of such measurements as they have bothered to make.[2]

Hippocrates started the trouble by teaching that at term the fetus, by the use of his hands and feet, ruptured the membranes and worked his way through the birth canal under his own power, the principal maternal contribution being a separation of the symphysis, which allowed the birth canal to stretch as the fetus passed through it. As Eastman points out, "The . . . concept . . . that the pelvis is an elastic ring capable of enlarging as necessary to permit passage of the infant would naturally nullify . . . any thought that narrowness of the bony passages . . . could impede the birth of the infant. In other words, any case of difficult labor which in modern times would be attributed to contracted pelvis was ordinarily explained before 1700 on the grounds that the ligaments of the pelvis failed to stretch. With this idea of the mechanism of labor in mind, there could be no such thing as dystocia due to contracted pelvis as we understand the term, and pelvic mensuration would be . . . quite meaningless. It would have been . . . about as significant as measuring the lumen of the nonpregnant cervix in order to ascertain if a full-term infant could pass through it."

It is true that before 1600, Vesalius[3] and Arantius[1] had maintained dogmatically that neither in women nor in animals was there the slightest evidence of separation of the symphysis during labor, but in those days anatomy was anatomy

The Russell D. Carman Memorial Lecture presented at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 7, 1948.

and obstetrics was obstetrics, and the old errors continued to be accepted in clinical circles for more than a hundred years.

In the year 1701, Hendrik Deventer recognized contraction of the pelvis as an important cause of dystocia, and in 1722 de la Motte named smallness of the inlet as the most important type of contraction, but it remained for Leveret in 1753 and William Smellie in 1754 to actually measure the pelvic dimensions of pregnant women and put those measurements to obstetrical use.

If Smellie's internal physical pelvimetry had remained alone in the field, the advent of x-rays in 1895 probably would have been followed by the rapid and widespread acceptance of x-ray pelvimetry, because obviously the patient would have been safer and the measurements more accurate if a beam of x-rays passing through the abdomen were substituted for a hand or caliper introduced through the vagina. Unfortunately, however, the year 1775 saw the introduction of Baudelocque's easier but far less dependable external pelvimetry. In retrospect, it is hard to understand the complacency with which obstetricians followed Baudelocque's teachings during the next century and a half without bothering to discover their inadequacy. They were accepted, however, and years later their acceptance delayed the development of x-ray pelvimetry because, unlike internal physical pelvimetry, external mensuration was easy and devoid of direct injury to the patient. Of course, it had one overwhelming fault, namely, failure in many cases to give accurate information as to the size of the birth canal, but it took Baudelocque's followers 150 years to discover that fault.

A most important factor in exposing the inadequacy of external pelvimetry has been the introduction of x-ray measurement, and obstetricians have been as active as radiologists in this work. In many localities, however, the radiologist is not equipped for pelvic measurement, and, on the other hand, one occasionally finds overenthusiastic x-ray workers who place too much emphasis on x-ray pelvimetry and underestimate the importance of good obstetrics. The pregnant woman who receives the care of a competent obstetrician and also a competent radiologist is twice blessed; she who has an experienced obstetrician but no radiologist at all has little to fear in most cases; but unfortunate indeed is the one whose obstetrician is incompetent regardless of the quality of the radiology that may be available to her.

While, in the main, radiology has played a minor role in the practice of obstetrics, it is important to note that in the United States alone there are several centers where x-ray pelvimetry has been employed skillfully and freely for many years. As to methods, surely there is no dearth. Some hundreds have been described, and there is a new flock each year, but all can be reduced to one of four fundamental approaches, and most allegedly new methods are really rediscoveries of old ones.

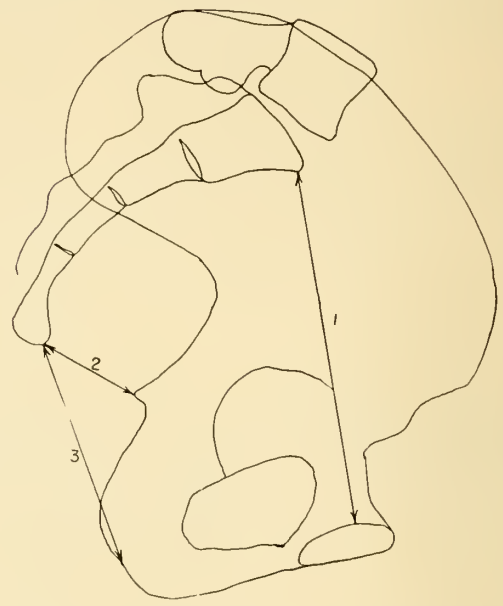

Fig. 1. Pelvic dimensions seen in the lateral view. (1) AP diameter of inlet. (2) Posterior sagittal of mid pelvis. (3) Posterior sagittal of outlet.

At the Chicago Lying-In Hospital we are engaged in a project calculated to answer such questions as:

1. Should x-ray pelvimetry be included as part of the routine examination of all primiparas?
2. If not, then what are the clinical criteria that call for it?
3. What pelvic dimensions should be measured?
4. What is the normal range of these dimensions?
5. How much below normal must these dimensions fall before the obstetrician is warranted in foregoing a test of labor and proceeding directly to surgical delivery?

A thousand consecutive primiparas are being examined by us; several different physicians and

technicians are engaged in the work, and we are measuring the pelves as completely as possible. Under such conditions, accuracy and objectivity are essential, and the expenditure of considerable

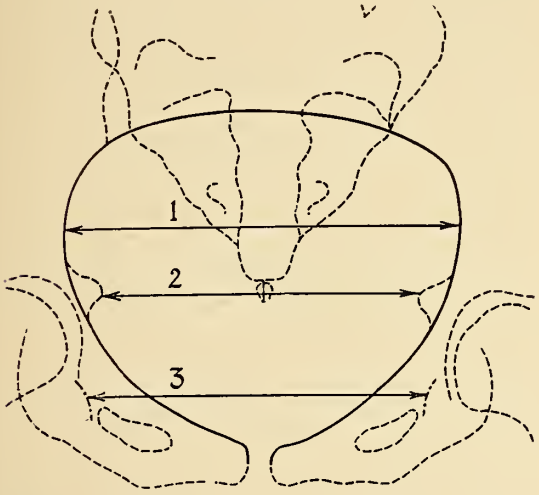

Fig. 2. Pelvic dimensions seen in the frontal view. (1) Transverse diameter of inlet. (2) Transverse diameter of mid pelvis. (3) Transverse diameter of outlet.

time and money upon special equipment is justifiable and even actually economical. I shall have failed in one of the purposes of this talk, however, if I lead you to believe that elaborate special equipment is essential to good work in those laboratories in which pelvimetry is done only occasionally.*

Pelvic Dimensions Seen in the Lateral View

In an ordinary lateral roentgenogram (Fig. 1) the end points of three important obstetrical diameters can usually be made out; but because of the phenomenon of divergent distortion, measurements of the images of these diameters are greater than the diameters themselves. The diameters in question are:

1. The obstetrical conjugate, which is measured from the sacral promontory to the most prominent point on the posterior surface of the pubic symphysis.

2. The posterior sagittal of the mid-pelvis, which is measured from the mean position of the images of the tips of the two spinous processes to the nearest point on the sacrum.

3. The posterior sagittal of the outlet, which is measured from the mean position of the posterior surfaces of the right and left ischial tuberosities to the nearest point on the sacrum.

*As presented at the June meeting, this portion of the paper was followed by the showing of twenty-eight lantern slides and a discussion of the fundamental aspects of many of the pelvimetry methods that have been published from time to time. In the present publication only three of the lantern slides are reproduced (Figs. 1, 2 and 3), and description of technical details has been reduced proportionately.

Pelvic Dimensions Seen in the Frontal View

In the frontal view (Fig. 2), that is, in a roentgenogram made with the patient lying on her back, three more significant pelvic diameters can be seen:

1. The transverse diameter of the inlet.

2. The interspinous diameter, which is the transverse diameter of the mid-pelvis.

3. The intertuberous diameter, which is measured between the right and left crescentic lines which represent the vertical medial surfaces of the right and left ischial tuberosities.

This latter is the transverse diameter of the outlet.

In order to measure these six dimensions in laboratories where there are only occasional calls for pelvimetry, my own preference is to make a single lateral 10-inch by 12-inch roentgenogram that carries the image of an isometric scale and a pair of stereoscopic frontal 10-inch by 12-inch roentgenograms in which the amount of the tube shift (K) is known and which carry register marks so that the films can be superimposed for the measurement of parallax. The films themselves can be made by any x-ray technician using any type of commercial x-ray equipment, and only two special accessories are required:

1. An isometric scale. This is a radiotranslucent rod or strip about 20 cm. long and calibrated at ½ cm. intervals by embedded lead shot or other opaque markers. The scale must be provided with a suitable mount so that it can be stationed between the x-ray tube and the film exactly in the mid-plane of the patient's body. Several commercial scales have been advertised, and innumerable homemade scales have been published.

2. A register marker. For convenience, we designate as the optical center of a roentgenogram that point near the center of the roentgenogram which lay perpendicularly below the target of the x-ray tube when the target was in its mean position midway between the extremes of the stereoscopic shift. Since cassettes fit loosely into grid trays, grids fit more or less loosely into the tracks in which they run, and films fit loosely into cassettes themselves, it follows that the optical centers of a pair of stereoscopic roentgenograms seldom coincide exactly with their geometric centers and a marker of some sort is necessary if the optical centers are to be identified. A satisfactory and inexpensive register marker can be prepared from a sheet of tempered masonite ¼" thick, 20" long and as wide as the x-ray table that is to be used. This sheet must be equipped with lugs or clips

or clamps by means of which it can be attached quickly and securely to the table top. The details of design will vary with the particular apparatus with which it is to be used, but any qualified x-ray serviceman should be able to make a marker suitable for his com-

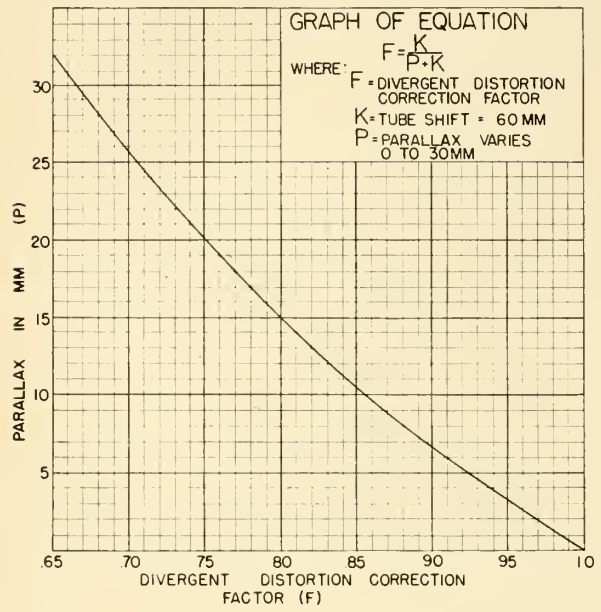

Fig. 3. Graph for obtaining divergent distortion correction factor (F) from measured parallax (P) in a pair of stereoroentgenograms made with a tube shift (K) of 60 mm.

pany's equipment. Embedded in the masonite so that their crossing lies perpendicularly beneath the mean position of the target of the x-ray tube are two 10-cm. cross wires made of approximately 20 gauge lead fuse wire.

Making the Stereoscopic Frontal Films

Attach the register marker to the x-ray table and lock the tubestand in position so that the mean position of the target is perpendicularly above the center of the cross wires. Lock the grid in position so that the center of the grid tray lies perpendicularly beneath the center of the cross wires. These spatial relationships are critical but once they have been established, preferably with the assistance of a machinist, marks can be filed or sawed or stamped into the apparatus so that for subsequent examinations the setup will be simple and easy. The height of the target above the film, or in other words the target-film distance, is not a factor in the accuracy of the measurement but is determined by the radius of the grid that is used—in most American equipment, 36 inches.

Shift the tube away from its mean position as far as it will go toward the back of the table.

Work sheet for obtaining seven points on the curve defined by the equation, $F = \frac{K}{P + K}$

Where K = 60 mm.
and P varies from 0 to 30 mm.

Where	P = 0	$F = \frac{60}{0 + 60}$	$= \frac{60}{60}$	= 1.000
Where	P = 5 mm.	$F = \frac{60}{5 + 60}$	$= \frac{60}{65}$	= 0.923
Where	P = 10 mm.	$F = \frac{60}{10 + 60}$	$= \frac{60}{70}$	= 0.857
Where	P = 15 mm.	$F = \frac{60}{15 + 60}$	$= \frac{60}{75}$	= 0.800
Where	P = 20 mm.	$F = \frac{60}{20 + 60}$	$= \frac{60}{80}$	= 0.750
Where	P = 25 mm.	$F = \frac{60}{25 + 60}$	$= \frac{60}{85}$	= 0.706
Where	P = 30 mm.	$F = \frac{60}{30 + 60}$	$= \frac{60}{90}$	= 0.666

Place a 10-inch by 12-inch loaded x-ray cassette in the grid tray and have the patient lie supine on the table with the center of the pelvic inlet approximately over the center of the film. Secure her in place by means of a compression band. Now make the first exposure. Then shift the tube forward through its mean position as far as it will go in the forward direction, insert the second film and make the second exposure. Note that the tube shift should be across the midline of the patient. In most apparatus this will mean that it is also across the strips in the grid, which makes for slightly greater absorption in the grid than when the shift is longitudinal. This loss by absorption is negligible, however, and, as we shall presently see, transverse shift has an important advantage in the measurement of the transverse diameter of the inlet. The exact amount of the stereoscopic shift (K) does not affect the validity of the measurement, provided (a) it is parallel to the plane of the film and always of a known and constant amount, and (b) that the parallax graph has been drawn for the particular tube shift that is being used.

The graph illustrated in Figure 3 has been drawn for a tube shift (K) of 60 mm. and the work sheet shows how the seven points on the curve were established. If the shift available in a particular x-ray apparatus cannot be adjusted until it is exactly 60 mm., one may draw a new curve through seven new points obtained from a work sheet in which the new K (measured in mm.) is substituted for 60 mm.

Work-up of Frontal Films

In the completed films, identify the right and left margins of the pelvic inlet, the right and left ischial spines and the right and left ischial tuberosities, and by means of a small sewing needle make holes in the film to identify these six points in both of the films. Now superimpose the films so that the two shadows of the cross wires coincide and passing the needle point through the holes in the front film make six more holes in the rear film. The rear film now has two needle holes for each of the six anatomical parts in question and the measured distance between the pairs of holes constitutes the parallax or P for each of these points. From the parallax graph (Fig. 3) determine the correction factors for the right and left ends of the pelvic inlet, add the two factors together and divide by 2 to obtain the mean factor. Measure the gross transverse diameter on both films, add the two diameters and divide by 2 to obtain mean gross transverse diameter. Multiply mean gross transverse diameter by the mean correction factor for this diameter, thus obtaining the net or actual transverse diameter. By similar means obtain net interspinous and net intertuberous diameters.

The following are probably not far from the average normals for these three dimensions:

Transverse diameter of inlet	13.5 cm.
Interspinous	10.5 cm.
Intertuberous	10.0 cm.

Making the Non-Stereoscopic Lateral Film

Lock the tube at the mean position midway between extremes of the stereoscopic shift so that the target lies perpendicularly above the center of the cross wires in the marker.† Arrange the patient on her side on the x-ray table with the center of the pelvic inlet approximately above the center of the film and secure her with a compression band. Fix the isometric scale in position so that it is close to the patient's back, parallel with the plane of the film and in the plane of the spinous processes and make a single exposure.

Work-up of the Lateral Film

In the completed film, set calipers on the obstetrical conjugate, and then transferring them to the image of the isometric scale, read the separation of the caliper points in half centimeters and estimated smaller fractions of a centimeter. By the same means, measure posterior sagittal of the mid pelvis and posterior sagittal of the outlet.

The following are probably not far from the average normals for these three dimensions:

Obstetrical conjugate	10.5 cm.
Posterior sagittal of mid pelvis	4.0 cm.
Posterior sagittal of outlet	5.0 cm.

SAN FRANCISCO DOCTOR PRESENTS HIS OWN PROGRAM

In this day and age when everybody is talking himself hoarse about medical plans and programs, Dr. Anthony B. Diepenbrock of San Francisco comes up with his own 13-point health program:

1. Continue to sit on your fat derriere and do nothing.

2. Be apathetic and, like 5,000,000 registered Republican voters who failed to vote, do not bother to make your opinion known. If you think, as they did, that your opinion or your vote is not worth anything, the opposition will agree with you and act accordingly.

3. Write an occasional letter to your congressman, tell him off, and then explain proudly to the interns in the surgical dressing rooms how smart you are and what a stinker your congressman is.

4. Tell everybody you see that the gag is up, and we might as well prepare for the inevitable.

5. Moan and groan and issue explosive and unprintable epithets.

6. Refer to your medical leadership as a group of impotent, ineffective and bumbling ignoramuses.

7. Make speeches before sympathetic lay audiences, and convert those who already believe in free enterprise.

8. Don't bother to tell your county society heads, your state society heads, or your national association heads what you want them to do. Expect them to find a way for you without your guidance.

9. Scream about high medical society dues and forget that our friends in the trades unions demand many times what we pay: in other words, make the situation as difficult as possible, then grumble about it.

10. Oppose any program developed by the majority of your colleagues because it demonstrates your superior wit and your general greatness.

11. Remain superbly and learnedly dignified when Joe Doakes asks why you oppose state medicine. Brush him aside with any insult you can think of.

12. Don't bother to use the selling methods which actually bring messages before the public. Continue to depend on occasional radio feature programs. Billboard advertising, newspaper advertising, national magazine advertising, radio advertising and above all, continuous and daily radio spot programs over national hookups and all such like are too commercial, too troublesome, to expensive and too undignified: don't use them.

13. Above all, disregard the "little guy"—the one with a vote. Tell him nothing; push him around. He doesn't know anything anyhow.—A.M.A. Secretary's Letter, November 29, 1948.

SURGERY OF THE VEINS OF THE LOWER EXTREMITY

ROBERT R. LINTON, M.D.
Boston, Massachusetts

RAPID STRIDES have been made in recent years in the treatment of diseases of blood vessels. The surgery of arteries has received most of the attention in the surgical literature, whereas that of the veins has been neglected somewhat. The apparent lack of interest in this branch of vascular surgery, despite the frequency of disorders of the veins of the lower extremity, is perhaps due to the fact that the results of treatment of conditions involving them have been, for the most part, unsatisfactory. Furthermore, practically any major vein with the exception of the superior vena cava, the inferior vena cava proximal to the renal veins, the portal vein and the right renal vein may be interrupted without serious consequences, whereas the viability of a part supplied by a major artery is so dependent on the arterial blood supply that naturally much interest has developed in maintaining it.

The veins of the lower extremity consist of three separate groups.

1. The superficial veins, which lie between the skin and the deep fascia in the subcutaneous tissues. These consist of the internal or long saphenous vein, which runs upward in front of the internal malleolus along the inner side of the leg, passing behind the inner side of the knee and continuing up the thigh to enter the fossa ovalis just below the inguinal ligament to join the common femoral vein. The external or short saphenous vein extends from just below the external malleolus up the outer side of the ankle and along the mid-line of the calf, passing through the deep fascia usually near the lower end of the popliteal space to join the popliteal vein behind the knee. These two systems of veins intercommunicate through numerous of their branches, so that frequently pathological conditions of one may involve the other.

2. The deep veins of the lower extremity consist of the common femoral, superficial and deep femoral veins in the thigh. In the lower leg the posterior tibial, anterior tibial and peroneal veins join to form the popliteal vein at the knee.

3. The communicating system of veins. There are numerous communicating veins, which connect the deep system with the superficial ones. Normally these vessels contain valves which permit blood to flow only from the superficial to the deep system. The superficial and deep veins also contain valves at frequent intervals which normally permit blood to flow towards the heart.

The most common diseases involving these blood vessels are: (1) varicose veins of the superficial system; (2) thrombosis of the superficial or deep systems; (3) postthrombotic sequelae of the lower extremity secondary to incompetency of the venous valves of the superficial, deep and communicating systems of veins.

Varicose Veins

Varicose veins of the lower extremity are probably one of the most common of human ailments. The most frequent symptoms referable to varicose veins are pain, dermatitis, ulceration, faintness due to the reduced circulating blood volume when the patient assumes an erect position because of pooling of the blood in this large stagnant venous reservoir, and, finally, the cosmetic appearance, considered by some female patients as a very important symptom. Varicose veins of the lower extremity develop because of dilatation —that is, an increase in the diameter—of the saphenous vein from the hemostatic pressure of blood resulting from man's erect position. This results in incompetency of the venous valves, due to incomplete apposition of the valve leaflets since they do not increase correspondingly in size. The process, as a rule, commences in the upper portion of the thigh at the saphenofemoral junction and extends distalward. If treatment is not instituted the whole system of superficial veins may become varicosed in time because of the lack of support from the fascial covering, such as encases the leg, which prevents the deep veins from dilating.

A number of tests have been devised to de-

From the Department of Surgery, Massachusetts General Hospital.

Oration given at twenty-sixth anniversary meeting of Minneapolis Surgical Society, March 16, 1948.

termine which system of veins is involved in a given case of varicose veins. The most useful one of these is the so-called Trendelenburg or tourniquet test. The author's modification of this test is performed by having the patient lie down. The extremity is elevated to empty the veins of blood, then a rubber venous tourniquet is placed around the leg just below the knee (Fig. 1). The patient then stands erect. Careful observation of the veins distal to the tourniquet is made. If slow filling of them with blood occurs before removing it and rapid filling after it is removed, the varicosities for the most part are due to incompetency of the superficial system of veins. Another satisfactory method of testing this system of veins is by finger pressure over the internal saphenous vein at the knee and the external saphenous vein in the popliteal space. It is possible by this means to determine whether one or both of these veins is incompetent. If the veins fill rapidly as soon as the patient assumes the erect position with the tourniquet placed below the knee, it is proof that the deep and communicating systems of veins have incompetent valves. As a rule when this observation is made it will be found frequently that the superficial system is incompetent as well. A previous history of a deep venous thrombosis of the extremity is usually obtained with these findings.

Fig. 1. Tourniquet test to determine the competency of the valves of the superficial, deep and communicating systems of veins. The absence of filling of the varicose veins distal to the tourniquet indicate the valves of the deep and communicating veins are competent, and that the varicose veins are the result of incompetent valves in the saphenous veins. (See Fig. 4A for the extent of the varicose veins.)

Treatment

Numerous forms of treatment for varicose veins have been devised. It appears from the surgical literature that one method is in vogue for a short period of time and then is discarded for another. In fact the treatment has apparently gone around in circles, coming back many years later to one of the earlier forms of treatment. For example, at the Massachusetts General Hospital from 1835 to 1845, numerous patients were admitted to the surgical wards for the injection of their varicose veins with a solution of ferric chloride. The results of this form of therapy were never published and presumably it was abandoned because of serious complications. This treatment apparently was then discarded but rediscovered around 1925 to 1930 and it again became the recognized form of therapy, except a different type of sclerosing solution was used.

In the early part of this century various types of surgical operations were devised. The most commonly practiced one was called the stripping operation. Babcock[2] devised an intraluminal type of stripper, whereas Mayo[13] described a perivenous type. Both had their advocates but the intraluminal type has proven to be the more effective. This form of therapy was discarded in the late 1920's because of a definite mortality rate from sepsis and pulmonary embolism, and the introduction of the injection therapy which could be performed on the ambulatory patient without hospitalization. It soon became apparent that this treatment was unsatisfactory from the patient's point of view because of the high incidence of recurrence of the varicose veins. In addition the treatment was unsatisfactory in many cases because of the discomfort and incapacitation to the patient. Due to the temporary benefit from this form of therapy, a high interruption of the saphenous vein at the saphenofemoral junction with a retrograde injection of a sclerosing solution at the time of the operation then came into vogue. Many surgeons still perform this type of procedure, but it also has been found to

be inadequate because of a high recurrence rate and in some cases deaths have occurred due to the production of deep venous thrombosis with secondary pulmonary embolism. The recurrences

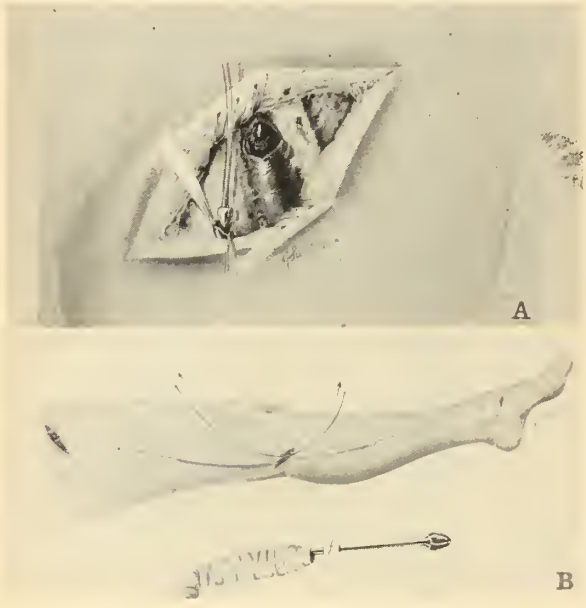

Fig. 2. The technique of stripping the internal saphenous vein. (*a*) The vein has been ligated and divided at the sapheno-femoral junction. (*b*) One stripper is passed distalward to the knee level and this section stripped from above downward after ligating the vein to the stripper at the proximal end. A second stripper is inserted upward from the ankle, and the vein in the lower leg is stripped up to the knee. The inset shows the saphenous vein folded accordion-like on the stripper. Large varices often invert in stripping, in which case they are more likely to break, necessitating additional incisions.

following this form of treatment occur chiefly because the sclerosing solution for the most part produces only a thrombus which later absorbs and the vein canalizes. In addition to thrombosing the superficial system of veins, frequently the communicating veins also are thrombosed. Edwards[6] has pointed out that the venous valve is damaged by venous thrombosis and becomes incompetent following canalization of the vein so that frequently the recurrences have been found due to the incompetency of communicating veins which, prior to the retrograde injection, had competent valves.

Because of these disadvantages in the treatment of varicose veins by injection, and the ligation and retrograde injection methods, a combination of ligation and stripping of the main trunk or trunks of the internal and external saphenous veins has been performed during the past decade in our clinic for patients with varicosities of the superficial veins. The procedure has been performed in over 500 patients without a death and deep thrombosis occurred only in one patient. The operation is performed under a general anesthetic, preferably ether, because it is a safe anesthetic. Since varicose veins are rarely a lethal disease, the safest method of anesthesia should be utilized. The internal saphenous vein is isolated, ligated and divided at the saphenofemoral junction proximal to its upper tributaries. An intra-

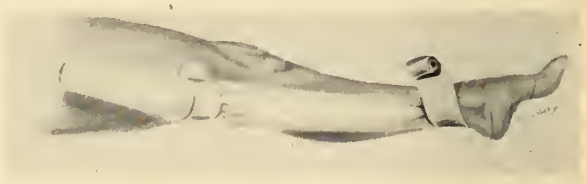

Fig. 3. Postoperative dressing. Small dressings are applied to the incisions, then a large gauze roll is held in place with three strips of adhesive tape over the course of the internal saphenous vein. The extremity is then wrapped snuggly with two 4-inch elastic gauze bandages from the toes to the groin to control bleeding from the tributaries of the saphenous vein. The bandages and gauze roll are removed in forty-eight hours.

luminal type of stripper is inserted into the proximal end of the internal saphenous vein and passed downward to just below the knee. The internal saphenous vein is then exposed just distal to the internal malleolus and another intraluminal stripper passed upward (Fig. 2). Occasionally it will go up a second trunk, which may extend as far as the upper third of the thigh. The vein is tied to the end of the stripper and then it is pulled out along with the stripper. It is preferable to strip the thigh section from the groin to the knee and the lower leg portion from the ankle to the knee. The patient is always in Trendelenburg position during the stripping procedure; that is, the feet and legs are at a higher level than the heart, to reduce the venous pressure and thereby minimize the bleeding from the tributaries of the main saphenous trunks which are torn but not ligated. If the vein breaks during the stripping process it may be necessary to make additional incisions to complete the removal of the veins. If the external saphenous vein is incompetent, the patient is placed in the prone position and the vein exposed just behind the external malleolus. The stripper is inserted from below upward to the popliteal space. Then through a transverse incision the proximal end of the main trunk is isolated be-

neath the popliteal fascia. It is ligated and divided at the saphenopopliteal junction. Great care should be exercised not to damage the posterior tibial and peroneal nerves, especially with metal retractors, while performing this part of the procedure. The distal end of the vein is tied to the stripper and the vein removed by stripping from the ankle to the popliteal space. The popliteal fascia should be sutured carefully to prevent herniation of the politeal fat, which, if it occurs, is very unsightly, especially in a woman's leg. A pressure dressing, consisting of a large gauze roll held in place over the course of the internal saphenous vein with a few strips of adhesive tape, is applied and then the leg bound with an elastic bandage from the toes to the groin (Fig. 3). The patient is made ambulatory on the first postoperative day, walking at least five minutes every two hours. The pressure dressings are removed on the second postoperative day and the patient may go home or remain in the hospital a few more days to have the skin sutures removed. The patients are not allowed to sit in a chair except for very short periods of time for at least a week following the operation because of the danger of deep venous thrombosis following the operative procedures on the lower extremities. Since all the dilated tributaries of the saphenous vein are not removed by this process of stripping, it is necessary to supplement this form of therapy with a few injections of a sclerosing solution. This is done in the office following the recovery from the operation.

Fig. 4. (*A*) A preoperative photograph showing bilateral varicose veins of the internal saphenous system of veins. The large tortuous variety in the left leg is not the main saphenous but an enlarged tributary. Note the pigment changes in the skin of the left lower leg in which previous ulcerations had developed.

(*B*) A postoperative photograph showing the same extremities 18 months after operation. The large tortuous varicosity in the left leg was excised in the thigh through three small transverse incisions since it is impossible to strip this type of vein because of its tortuosity and the fact it is so adherent to the skin. In addition the long saphenous veins were stripped from the groins to the ankles. One injection of a sclerosing solution was given postoperatively, in the right leg and four in the left leg. Note the absence of varicose veins and the improvement in the pigmentation of the skin of the left lower leg.

The results of this type of therapy have been very gratifying (Fig. 4) but no patient is promised that his varicose veins will be cured. He is warned that others may develop, which may need subsequent injection. An occasional patient with recurrent or persistent varicose veins will be found in which a second trunk of the internal saphenous vein or an incompetent external saphenous vein has been overlooked, in which case

another surgical procedure should be performed to remove these vessels.

Deep Venous Thrombosis of the Lower Extremity

Thrombosis of the deep veins of the lower extremity is a serious complication which develops most frequently after major surgical operations, trauma to the lower extremity, pregnancy, and serious illnesses such as heart disease, pneumonia, and typhoid fever. The relationship of deep venous thrombosis to pulmonary embolism has long been established. In 95 per cent of the cases it is believed approximately all pulmonary emboli can be traced to the leg veins.[7] Early ambulation and the use of the anticoagulants, dicumarol and heparin, are effective measures to prevent this condition. The accepted method of treating deep venous thrombosis in our clinic at the Massachusetts General Hospital once it has developed is to interrupt the femoral veins in the groin. We believe that if a diagnosis of deep venous thrombosis of the lower extremities is made, or if a patient has had a non-lethal pulmonary embolus, irrespective of whether or not the legs show signs of venous thrombosis or phlebitis, this is the best method of therapy.[1] It prevents further embolisms in the majority of cases and at the same time it protects the extremities from the post-thrombotic sequelae seen so frequently in the patient who has not had the femoral veins interrupted.

This method was first described by Homans[8] in 1934. During the past decade we have interrupted the femoral veins in 2,131 patients up to January, 1948. No serious sequelae have resulted from the operation and only in a few instances has an ulcer developed in the extremity. It is believed many lives have been saved and the morbidity of the disease greatly reduced. The operation of femoral vein interruption is a surgical procedure which can be performed readily, using local infiltration of a 1 per cent procaine solution. It is imperative, however, that the surgeon should be thoroughly familiar with the surgical anatomy of the blood vessels in Scarpa's triangle. The common femoral vein is a continuation of the external iliac vein. It extends distalward from the inguinal ligament for about 5 to 7 centimeters, where it bifurcates into the superficial femoral vein and the deep femoral vein. The former extends down Hunter's canal with the superficial femoral artery to become the popliteal vein and the deep femoral drains the blood from the posterior muscles of the thigh. The internal saphenous vein is the most proximal tributary of the common femoral vein and between it and

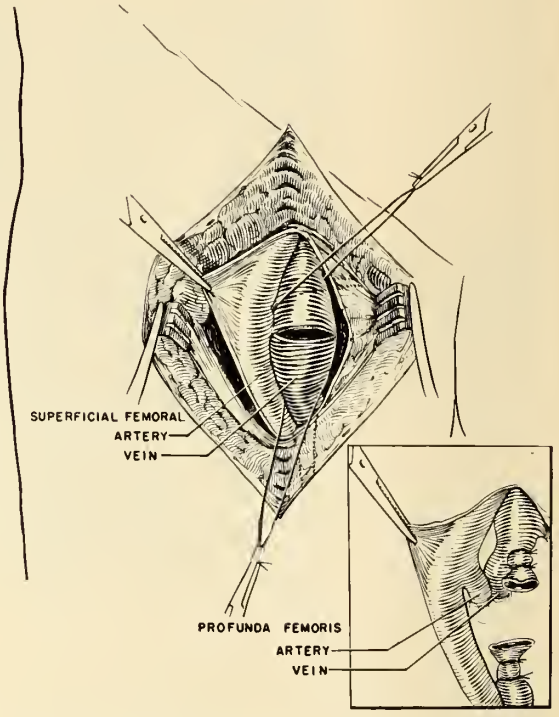

Fig. 5. Interruption of the superficial femoral vein. This artist's drawing shows the exposure of the right superficial femoral vein using a vertical incision, the upper end commencing at the groin crease. The dilatation of the vein localized the junction of the superficial and deep femoral veins. The femoral artery is retracted lateralward. The incision in the vein is indicated and should always be transverse. The inset shows the divided superficial femoral vein with both ends doubly ligated. The ligatures on the proximal end should be placed as close to the deep femoral vein as possible so that a blind segment of vein is not formed in which a secondary thrombus may develop and from which a pulmonary embolus might occur.

(Courtesy Mason, Robert L., and Zintel, H. A.: Preoperative and Postoperative Treatment. By permission of W. B. Saunders Company, publishers, Philadelphia.)

the origin of the deep femoral vein several other vessels arise from it, the largest of which are the medial and lateral femoral circumflex veins.

The common femoral vein should never be interrupted proximal to the saphenofemoral junction, nor should it and the internal saphenous vein be interrupted in the same extremity. This is because the collateral circulation at this level in some patients is so meager that serious results to the extremity have been observed and reported, one by Dennis[5] when the interruption was at this

level. Interruption of the superficial femoral vein just distal to the origin of the deep femoral has been found to be the safest level to interrupt the deep venous system in this region (Fig. 5). This is the routine procedure in our clinic if there is no thrombus encountered and if the patient can become ambulatory immediately after it is performed. If a clot is found in the common femoral it is better to interrupt the common femoral distal to the sapheno-femoral junction and proximal to the deep femoral vein (Fig. 6). This is a more difficult interruption because of the tributaries arising from it, which in most instances must be ligated separately, to give sufficient length of common femoral vein to safely ligate and divide. However, it protects the patient from emboli which may arise from the deep femoral vein, a distinct possibility if a thrombus was found proximal to it. The clot should be removed both distal and proximal to the opening made in the common femoral vein (Fig. 6) by aspiration. From experience it has been found that this can be accomplished readily if the venous thrombosis has been detected early so that the patient's thigh has not been swollen for more than forty-eight hours. If it has been for a longer period, the clot will be found so adherent that it will be impossible to remove it. Under these circumstances if the patient has had a pulmonary embolus a more proximal interruption of the venous system at the level of the inferior vena cava should be performed. If no embolism has occurred, conservative measures are recommended.

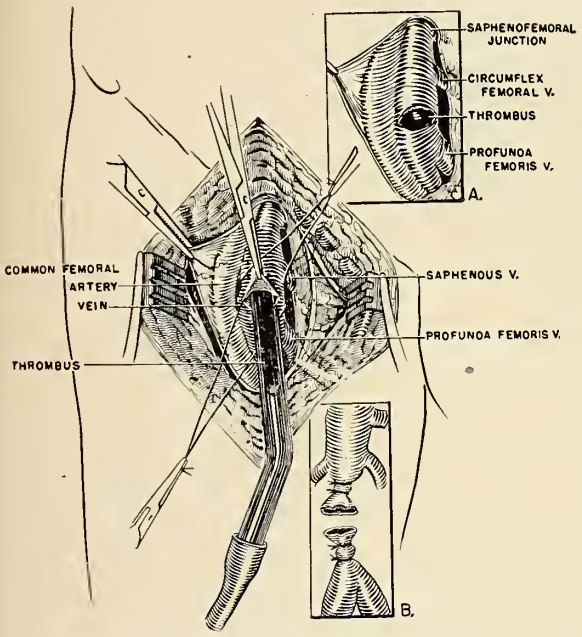

Fig. 6. Interruption of the common femoral vein with thrombectomy. An artist's drawing to show the exposure of the right common femoral vein. The upper end of the incision should be 2 cm. above the groin crease. The femoral artery is retracted lateralward. Two untied ligatures have been placed around the vein to control the bleeding after thrombectomy. The thrombus is removed by aspiration through a glass cannula. The proximal segment is always aspirated first. Inset A. shows the thrombus protruding through the transverse incision in the vein. Inset B. shows the completely divided vein with both ends doubly ligated with non-absorbable ligatures. The division is above the junction of the superficial and deep femoral veins.

(Courtesy Mason, Robert L., and Zintel, H. A.: Preoperative and Postoperative Treatment. By permission of W. B. Saunders Company, publishers, Philadelphia.)

The following practical suggestions concerning femoral vein interruption are worth enumerating: The incision should be a vertical one over the course of the great vessels in Scarpa's triangle (Figs. 5 and 6). Serious injury to the femoral artery has occurred in other surgeons' hands when this cardinal principle has not been followed because of the difficulty in obtaining adequate exposure of sufficient length of these large blood vessels. Two traction ligatures should be placed around the femoral vein before it is opened in order to control the bleeding. The femoral artery in patients subject to this disease, since they are usually over forty years of age, is a friable structure. For this reason it should not be freed up and retracted with a rubber tube because this may be sufficient trauma to fracture its wall to produce arterial thrombosis with resulting gangrene of the extremity. It should be retracted by traction on the periarterial tissues (Figs. 5 and 6). It is recommended that ligation and division of the femoral vein is preferable to ligation in continuity. This should be performed by ligation of each end with a primary ligature of non-absorbable material such as cotton or silk and a secondary transfixion ligature of the same material in the cuff of the vessel distal to the former.

Interruption of the venous system at a higher or more proximal level is indicated in a few instances. This may be done by ligation of the common iliac veins or the inferior vena cava distal to the renal veins. The latter is more practical since the large veins from both the lower extremities and the pelvis may be interrupted by ligation of this single large blood vessel. In

addition it can be performed through one incision, whereas bilateral common iliac vein interruptions necessitates two separate incisions, one in each lower quadrant.

centimeters above the umbilicus is recommended for ease of exposure. The rectus muscle is retracted lateralward, the peritoneum with its contents and the ureter are retracted medialward to

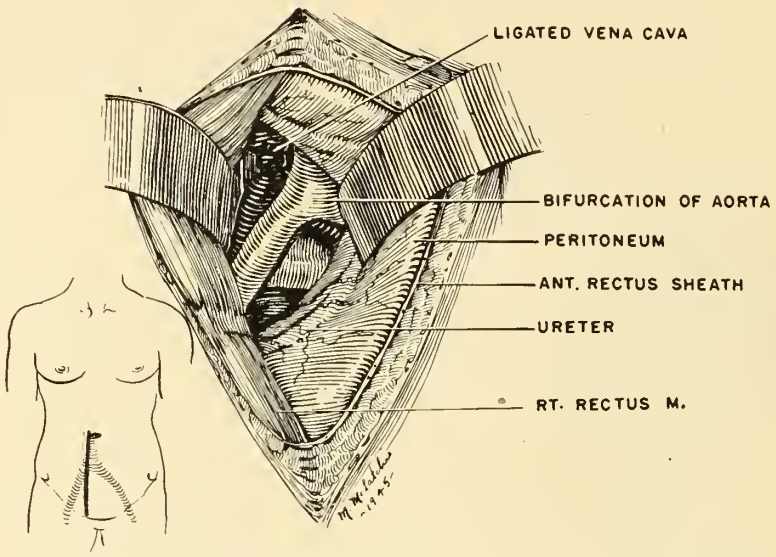

Fig. 7. Interruption of the inferior vena cava. An artist's drawing to show the extraperitoneal exposure and ligation in continuity of the inferior vena cava using a right paramedian incision. The rectus muscle is retracted lateralward and the ureter, peritoneum and its contents medialward. The incision extends from the pubis to about 5 centimeters above the umbilicus. For ligation, we use two non-absorbable ligatures of silk or cotton.

(Courtesy Mason, Robert L., and Zintel, H. A.: Preoperative and Postoperative Treatment. By permission of W. B. Saunders Company, publishers, Philadelphia.)

Ligation of the inferior vena cava in our clinic is restricted to a few patients. It is recommended: (1) in those patients who develop septic non-fatal pulmonary emboli arising from a septic thrombophlebitis of the pelvic veins; (2) in those who have had femoral vein interruption and dicumarol therapy but continue to have pulmonary emboli; and (3) in a rare instance of phlegmasia alba dolens complicated by non-lethal pulmonary embolism. It has been performed on sixteen patients in our clinic during the past ten years. When compared to femoral vein interruptions in 2,131 patients during the same period, the relative infrequency of it in our clinic can readily be seen. In a few instances of fatal pulmonary embolism following femoral vein interruptions, it is believed that the lives of some of these patients could have been saved by the timely interruption of the inferior vena cava. An extraperitoneal exposure of it is preferable to a transperitoneal one because it produces less surgical shock. A long right paramedian incision extending from the symphysis pubis to about 5

expose the bifurcation of the inferior vena cava (Fig. 7).

Interruption of it is performed by double ligation of it with strong non-absorbable material such as braided silk. The vessel is so large in diameter it would require freeing up too great a length of it to permit a safe ligation and division. Large veins in contradistinction to large arteries may be safely ligated in continuity, since their walls are less friable and the intraluminal pressure is much less. No serious sequelae have developed in our patients following inferior vena cava interruption, but it is believed the ones that have had it performed should be followed for a longer period before recommending the procedure except in the rare instance as already described. It should be pointed out that it is a major surgical operation compared to femoral vein interruption, and may carry a considerable mortality rate as evidenced by the results of Thebaut and Ward[14] who reported four operative deaths in thirty-six patients, a mortality rate of 11 per cent. When these figures are compared

to 2,131 patients who have had femoral vein interruptions in our clinic without a single operative death, it is obvious that this latter procedure is preferable in the average case of venous thrombosis of the deep veins of the lower extremities.

Postthrombotic Sequelae of the Lower Extremity

The most common postthrombotic sequelae of the lower extremity in order of frequency seen in eighty-four extremities were edema, varicose veins, pain, stasis dermatitis, stasis cellulitis and chronic ulceration. The treatment of these sequelae has baffled the medical profession for many years. None of them is a serious threat to the life of the patient, but many fortunes have been spent on inadequate treatment with little or no lasting benefit. The morbidity of them is high and if it were possible to estimate the time lost from work due to them it would undoubtedly be stupendous. It is believed, therefore, that radical surgical treatment, if it has any possibility of curing these conditions, should be performed.

The observation has been made that the postthrombotic sequelae except for pain and edema as a rule do not develop until the deep veins of the leg have canalized. Ulceration may occur even within a year of the original deep venous thrombosis but not before canalization of the deep veins. The observation that only in a rare instance, following therapeutic or prophylactic interruption of the femoral vein for thromboembolic disease, have the post-thrombotic sequelae developed, in approximately 2,000 patients who have had one or both femoral veins interrupted at the Massachusetts General Hospital in the past ten years, led the author to believe that interruption of this vein distal to the profunda femoris branch might benefit the postthrombotic sequelae. Buxton and Coller[3,4] and Homans[9] have also recommended this procedure. It is believed, however, in addition to interruption of the superficial femoral vein, the incompetent internal and external saphenous veins should also be removed by the method of stripping as already described. This form of treatment is recommended chiefly in those patients with early post-thrombotic sequelae, namely, pain, edema, varicose veins and beginning stasis dermatitis and was previously reported.[11] If, on the other hand, the condition has been long standing so that the extremity in addition presents marked dermatitis, stasis cellulitis and chronic ulceration, a still more radical form of surgical treatment may be indicated.

Fig. 8. Ligation of the communicating veins, excision of internal and external saphenous veins and fasciectomy. A longitudinal incision about one centimeter posterior to the tibia is made on the inner side of the lower leg from the knee to just below the internal malleolus. The medial group, or posterior tibial communicating veins, are ligated and divided. The deep fascia is divided at the posterior edge of the tibia to expose the internal saphenous vein, which is removed (*A*). The external saphenous vein is exposed by incising the deep fascia of the posterior skin flap and it also is excised (*B*). The sural nerve is carefully preserved. The saphenous nerve is usually removed with the internal saphenous vein. A large window of deep fascia is excised from the posterior flap. This gives lymphatic drainage to the subcutaneous tissues and permits easier closure of the wound. Interruption of the superficial femoral vein, ligation of the long saphenous vein at the sapheno-femoral junction and the stripping of it to below the knee should be done to complete the operative procedure in cases of post-thrombotic ulcers and induration of the lower leg. The ulcerations must be healed before performing this type of procedure.

Homans,[10] in 1917, described the method of excision of the chronic ulcer and most of the diseased skin around it, carrying the dissection

through the deep fascia down to muscle and periosteum, then applying an immediate split thickness skin graft to the raw surface. This method is still useful in some of the very old chronic ulcer cases but it leaves much to be desired as far as the cosmetic result is concerned, and in the cases in our clinic where this alone has been utilized, only 50 per cent have been cured. Interruption of the superficial femoral vein in these extremities has been found to be a valuable adjunct to this form of treatment. Recurrent ulcerations following the procedure have healed after superficial femoral vein interruption so it is now performed at the same time as the excision of the ulcer and the skin graft.

The author,[12] in 1938, described another method of treatment for this type of case which does not disfigure the extremity to the same degree as the excision and skin graft method. It has been modified somewhat since then with more satisfactory results. The procedure that is now recommended consists of interruption of the superficial femoral vein distal to the profunda femoris branch, ligation of the internal saphenous vein at the sapheno-femoral junction, stripping of this vessel in the thigh, ligation of the medial group of communicating veins of the lower leg through a long veritical incision extending from the knee to just distal to the internal malleolus, excision of the deep fascia on the posteromedial aspect of the lower leg and excision of the internal and external saphenous veins in the lower leg (Fig. 8). In order to prepare the extremity for this procedure, the ulcer is first healed, utilizing elastic adhesive bandages or an Unna's boot type of bandage. These are changed at weekly or biweekly intervals depending on the size of the ulcer. When the ulcer is epithelialized the patient is admitted to the hospital, where with bed rest and elevation of the extremity the condition of the skin is further improved. The operation is done under the protection of penicillin. Ether or spinal anesthesia is used. The femoral and saphenous veins are first interrupted in the groin, and the latter stripped down to just below the knee. The long vertical incision about 1 centimeter posterior to the tibia is carried down through the deep fascia. The large incompetent communicating veins arising from the posterior tibial vein are ligated and divided. The dissection is carried anteriorly over the tibia severing the attachment of the deep fascia to the bone. The internal saphenous vein is readily seen through the deep fascia. It is excised completely from the upper to the lower end of the incision by incising the deep fascia. The posterior skin flap is then raised and the short saphenous vein similarly removed. As large a section as possible of the deep fascia in the posterior skin flap is then excised. Care is taken to leave a small rim of it on the wound edge to aid in closing the wound with a layer of subcutaneous fascial sutures of fine chromic catgut. The sural nerve lying parallel with the external saphenous vein is preserved carefully. The excision of the deep fascia has a two-fold purpose. It permits closure of the long incision without tension and it reduces the amount of edema in the lower leg by giving better lymphatic drainage to the skin and subcutaneous tissues similar to the Kondoleon type of operation. After closure of the skin with fine interrupted silk sutures, a large gauze dressing is applied and outside this a plaster cast from the toes to the knee with the foot in ninety degrees dorsiflexion. Penicillin is continued postoperatively for five to seven days. The first dressing is done in ten days and if primary healing is obtained the patient is discharged home approximately two to three weeks after the operation with an elastic adhesive bandage over a large gauze dressing from the toes to the knee. This type of dressing is used for several weeks and then replaced with an elastic stocking or bandage until the edema has disappeared from the extremity. This may require from three to six months. The results by this method of therapy in the chronic indolent post-thrombotic ulcer cases have been found to be extremely gratifying both from the cosmetic standpoint and the healing of the ulcer.

Conclusions

1. The most common conditions of the lower extremities resulting from pathology of the veins are varicose veins, deep venous thrombosis and the post-thrombotic sequelae.

2. The surgery of these conditions, as performed in the Peripheral Vascular Clinic of the Massachusetts General Hospital, is reported.

THROMBOEMBOLISM AND THROMBOPHLEBITIS

HERMAN O. McPHEETERS, M.D.
Minneapolis, Minnesota

THIS SUBJECT of thromboembolism and thrombophlebitis has received such recognition in the medical press the past two years that one can hardly pick up one of the better medical journals without finding an article on it. Many of these have been written by men of wide experience, and regardless of what one's own experience or opinions may be one must stop and consider the subject in the light of their reports.

There are few of us who cannot recall the sad details of the doctor's mother who went to a large clinic to have a hysterectomy by the best man obtainable and who died of a massive pulmonary embolus as she got out of bed on the ninth day postoperative, or the fine wife of one of one's best friends who had a similar accident after a simple ovarian cyst resection, or the man with a hernia to whom one said, "Don't worry, it is very simple and you have nothing to worry about at all. In fact it will be just a good rest in bed with pretty nurses about you." But he died of the embolus just as you left the room, having told him to "go on home and have a good time." Or the executive, fifty-five years old, who was advised to take a few days' rest in bed at home after overwork, but who had his embolus while reclining on the cot in the sun parlor. These occurrences come from my own personal experience, and the patients are just as *dead* as though they had been shot with a rifle.

Both clinically and pathologically phlebothrombosis and thrombophlebitis are in a sense one and the same thing. They both mean a closure of the vein lumen with a blood clot.[2,18] It is just a question of the degree of the inflammatory phase of the condition present. Phlebothrombosis means just a closure of the vein with a simple blood clot like a post mortem clot. It is not fixed to the vein wall at all and stays in position only because of the stagnation of the blood stream and the branching of the veins. On the other hand thrombophlebitis means that there is an inflammatory phase present and because of this the thrombus is fixed and adherent to the wall of the vein so that seldom does it break loose and cause an embolus. This happens only as the inflammatory part of the picture disappears and the thrombus terminates in the simple red clot. In the presence of stagnation this may extend far along the vein and thus gradually pass over into the phlebothrombosis and it is this part that gives the embolus. You may say that this is "splitting hairs in diagnosis" yet that is just what we are trying to do. The true phlebothrombosis carries a very high incidence of mortality.[12,15] The true and marked case of thrombophlebitis has a very low one.[11] On the other hand, it causes much morbidity and oftentimes results in crippling for life.

There seems to be a very marked difference in the experience and opinion of the doctors in this area and of those in Boston. Much of the work and many of the opinions reported by various surgeons over the country reflect the influence of the Boston group.

The author, fully realizing how meager has been his experience as compared with that of many surgeons over the country, has thought it wise to briefly summarize some of these reports.

As Dr. McCartney[15] has shown, thromboembolism occurred most often in his series between sixty and seventy years of age. At the other extreme, we find Kleinsasser's series of 502 cases, from three army vascular hospitals with 54.6 per cent of his patients between twenty and twenty-nine years.[13] This of course could be accounted for by the type of patients handled in the latter group. He further reports that 81 per cent of the patients in Stich's series were over forty years of age, 66 per cent over sixty years of age, and 20 per cent over seventy years of age. Fifty per cent of the Miller and Rogers series were over fifty years of age. Veal and Hussy[27] reported 70 per cent of their series of eighty-four patients as over forty years of age. Allen, Linton, and Donaldson[2] reported 80 per cent in their series of 367 cases over forty years. Many other series are similar.

Bed rest is a most important predisposing cause. Research by Koch has shown that there is a definite slowing of the circulation time from eighteen seconds in the youth of fifteen to twenty years of age to twenty-three seconds in the age

Presented as part of a panel discussion on this subject in cooperation with Dr. J. S. McCartney of the University of Minnesota, Department of Pathology, and Dr. N. W. Barker of the Mayo Clinic, before the Minnesota State Medical Association, Minneapolis, Minnesota, June 7, 1948.

group of seventy years. This factor is further increased with the slowing and stagnation occurring with bed rest. The best report on this was by Hunter et al. They reported on two series of 200 autopsies each. In the first series the patients had been in bed for a period of time with absolute rest and no exercise of the calf muscles. Fifty-nine per cent of these patients were found to have thrombosis as compared with only 44 per cent in the other series of 200 patients who were *really* ambulatory or had used forced leg muscle exercise in the forty-eight hours before death.

Kleinsasser reports the trauma factor as present and active in 36.5 per cent of his cases. The trauma factor is then subdivided, showing that 21.7 per cent had crushing injuries of some type.

The general sickness factor causing 18.3 per cent of the entire number is subdivided, showing 49 per cent as associated with pneumonia.

The postoperative factor was present in 14.1 per cent of them all and when this is subdivided he shows 6 per cent of the total series as post appendectomy with 2 per cent after hernioplasty.

The lower extremity was involved in 92.9 per cent of cases compared to 7.1 per cent in the upper, and the left leg more often than the right. This he explains as due to the effects of gravity causing more stasis in the lower extremity. The vena cava lies to the right of the aorta and the right common iliac artery is thought possibly to cause some pressure on the left common iliac vein as it crosses it just below the bifurcation.

The deep veins were involved more often than the superficial. Swelling was the most common of the initial symptoms (84.5 per cent), but pain was the most prominent symptom in the majority of the cases. Pain was the first symptom in 34.8 per cent though not always the most prominent. Pulmonary infarct was present in 9 per cent of all cases though the first symptom in only 6.8 per cent of the cases. At the time of admission swelling was the most prominent symptom" with cyanosis next. The most common initial treatment before arrival at the center had been bed rest with elevation and the application of some type of heat. Then came sympathetic blocks and ligations. Ligations of the great saphenous vein was most common, then the superficial femoral and common femoral. After arrival at the center the most common treatment was conservative followed by lumbar block. The results were generally fine with only a moderate amount of partial disability and only 15.4 per cent needing continued support. This is an important point too often overlooked.

No discussion of this subject could be complete without reviewing the reports of Arthur W. Allen.[1] Without calling him radical, we must say that he and his associates have taken the lead in the active treatment of this condition. The surgeons and internists of this area do not agree with his reports, but they are so extensive that they must carry great weight. Though John Homans was the first to report the ligation of the femoral vein to prevent the propagation of the clot in thrombosis and phlebitis,[2,8,9,10] Allen and his associates have popularized it almost to the point of danger. The incidence of thrombosis and embolism in their experience is very high, occurring most often postoperative in hip fractures. This occurrence is so high that they recommend a prophylactic femoral vein ligation in all hip fractures requiring operation, in all patients above sixty years of age having major pelvic and abdominal surgery, and in those aged and debilitated patients requiring prolonged bed rest. This they advise to be done bilaterally. Their statistics, with 458 similar cases cared for with prophylactic ligation, as compared with a like number cared for without, certainly are convincing.

Their records show a marked increase in the number of ligations from year to year. In the five-year period of 1937 to 1942 they ligated only 202 patients while in 1946 alone they ligated over 500 patients. Today they do a prophylactic bilateral vein ligation in 42 per cent of their cases, while they formerly did ligations only after marked signs of thrombosis or when infarct pains had developed.

Gerald Pratt of New York has tried to follow a sensible middle ground.[23] I agree with his work most fully. His work was done at the New York Post Graduate Hospital and the St. Albans Navy Hospital. This shows a report on ninety cases of massive pulmonary embolism with seventy-four deaths. Ninety per cent of his patients were over forty years of age, with 30 per cent above sixty years, 15 per cent occurring on the medical services. On the surgical service *only* he found 33 per cent after gastric surgery, 19 per cent after gall-bladder operations and 13 per cent after appendectomy.

It is often difficult in the individual case to distinguish the thrombosis and thrombitis part of

the picture. His separation of the signs and symptoms is the best I have seen, and I want to approve of his listing of them. It is important to notice that the bland thrombosis may be present with little or no symptoms while the thrombitis case shows the evidence of the presence of the inflammatory factors, pain, redness, tenderness, and swelling.

Pratt does almost no prophylactic ligations. He does therapeutic ligations only when definitely indicated. Even Allen admits that he cannot tell with assurance which veins are involved so he just ligates them all. This is not logical. It may be simple for him and those well trained, but the average surgeon doing one now and then will most surely get into trouble and calamities will certainly follow. If the patient is having repeated emboli or has had a severe one and some localization can be made, then I would do a ligation. If there are no localizing signs a high vena caval ligation seems to be the only sensible thing to do. Other than this is meddlesome surgery when we have other such valuable and effective controls.[3,16,19]

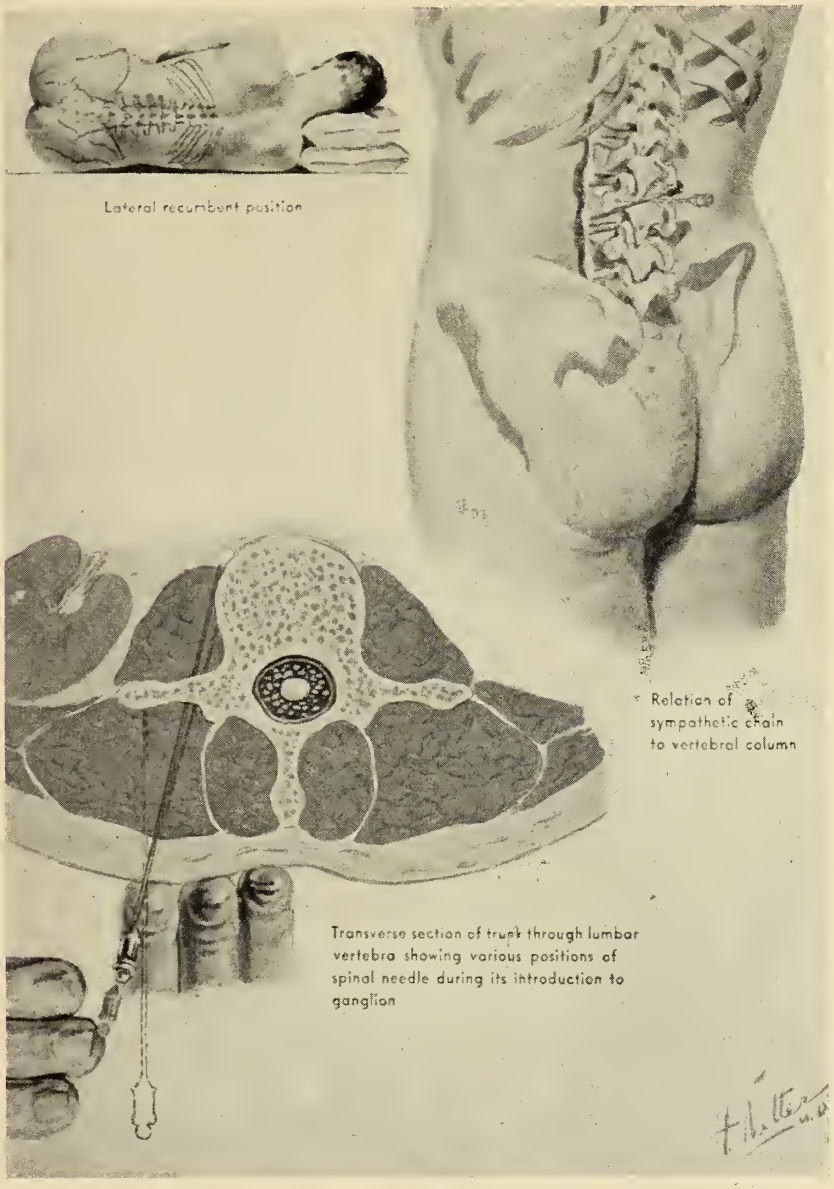

Fig. 1. Lumbar sympathetic block, after the technique of Ochsner.

In the acute thrombophlebitis case there is usually a marked reflex vasospasm.[19,20,21,22] For this condition the lumbar sympathetic block with

1 or 2 per cent novocaine is almost specific, and oftentimes the results and improvement are rapid and amazing. It should be done on every patient who shows any signs of vasospasm or pain. This is done with the Ochsner technique. I prefer to introduce the needles just a bit farther laterally. I am sure that I get better results with four needles than with one. It can be done under local anesthesia by injecting novocaine as the needle is inserted but it is much better to give some light anesthesia. It does hurt even with the best of technique (Fig. 1).

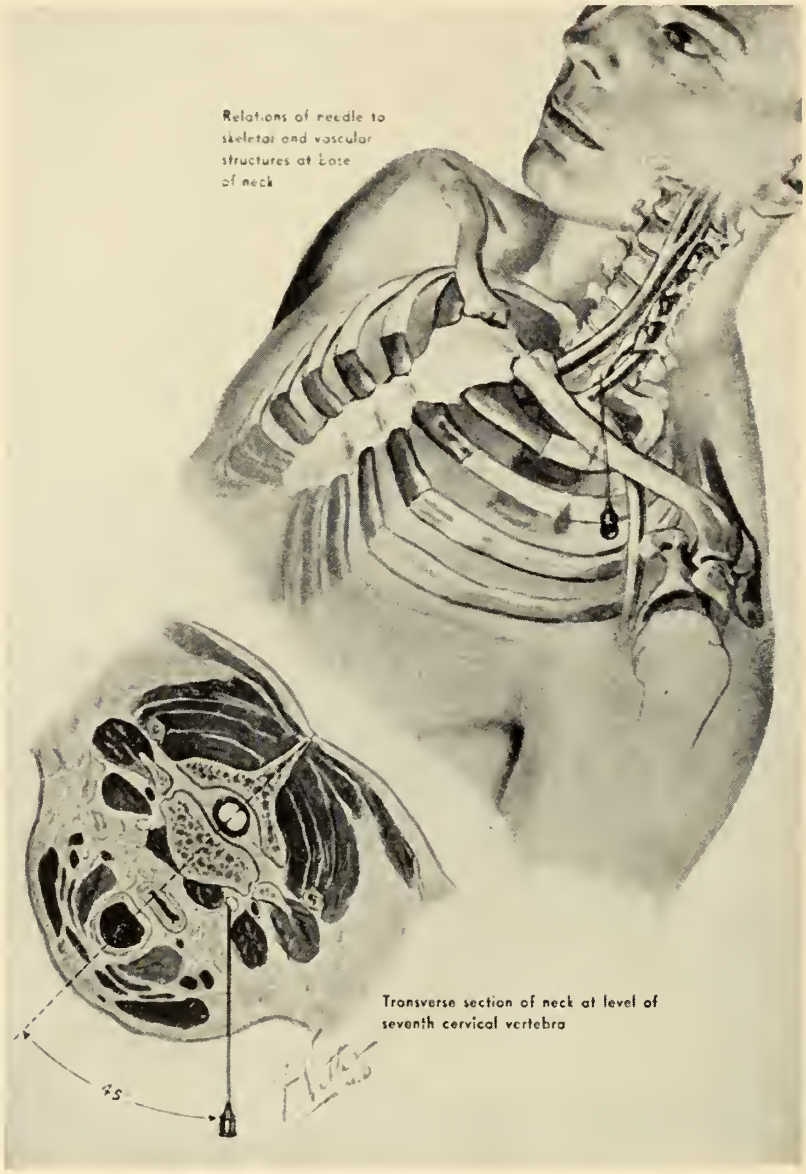

Fig. 2. Cervical sympathetic block—Ochsner

I cannot understand the lack of enthusiasm for the use of the lumbar sympathetic block in these cases. In my experience there has been complete relief or marked improvement in more than 90 per cent of acute cases. Much help is obtained even in the subacute and chronic case. Take the case of Dr. H., a dentist. This man, fifty-three years of age, had a deep femoro-iliac thrombophlebitis, of unknown cause in the left lower extremity, of eight weeks' duration. It was thought to be secondary to metastases to the retroperitoneal lymph glands. After one block and the application of routine hot packs the pain and swelling rapidly disappeared. He left the

hospital in eight days with a normal leg and the supportive bandage just for comfort. One week later he developed the same thing on the right side. The extremity was almost twice normal

The cervical sympathetic block should be used if the phlebitis has involved the upper extremity (Fig. 2).

I am convinced that the hot moist or Kenny

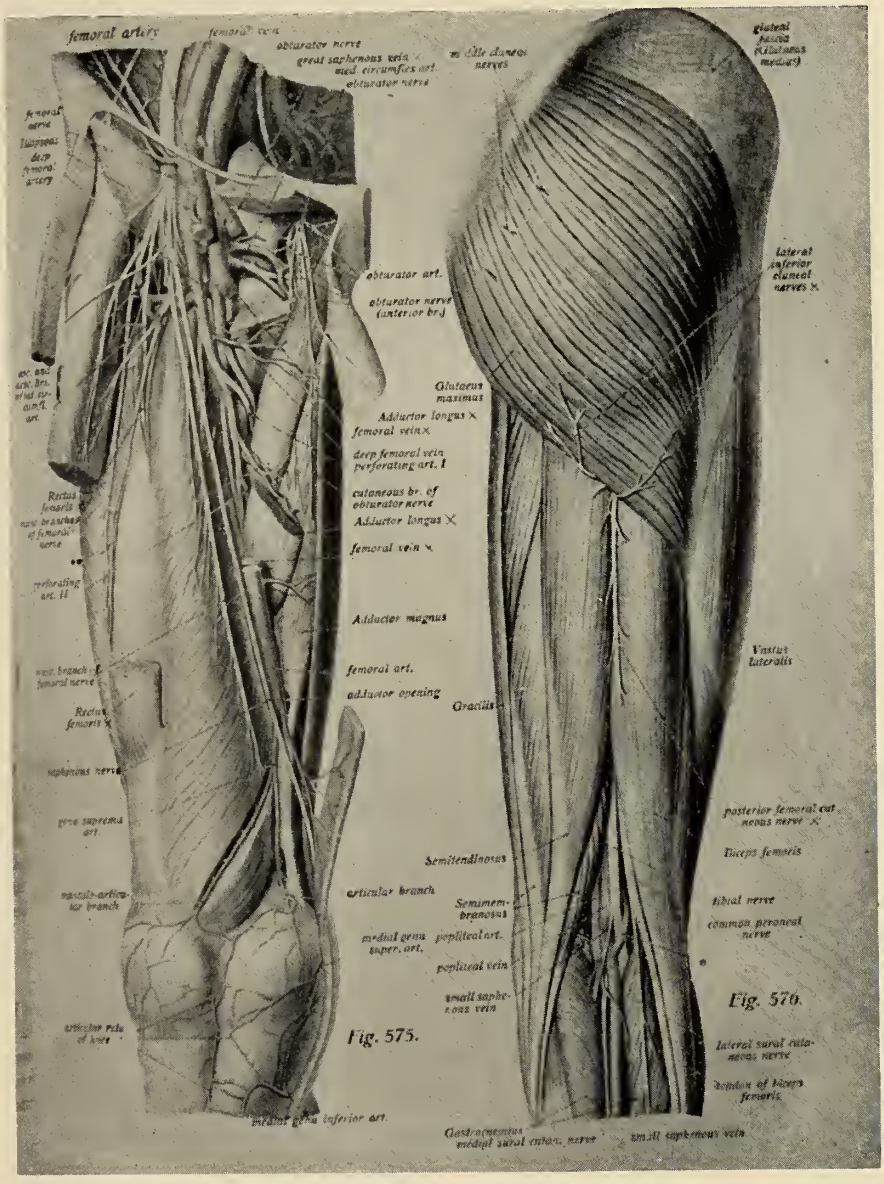

Fig. 3. Anatomy of the thigh, showing femoral veins. Taken from Sabotta anatomy.

size. Following two blocks and the routine packs it also returned to normal and he left the hospital two weeks from the date of the first block on that side with almost no swelling. I have advised him to wear a bandage just to be on the safe side.

With this same block and routine hot packs you can assure the patient, developing the usual postpartum or postoperative thrombophlebitis that he will be normal in one week.

pack is not used as often or as much as it should be for phlebitis. Unless it is well applied it is useless. If the blankets or towels are not wrung dry they are dangerous. It is the pack soaked with water that causes the burns. Carefully applied at a temperature of 125 to 130 the pack will not cause burns (See Instructions).

Research by Drinker[7] has shown that the lymphatic drainage is rapidly increased in the

presence of the hot moist pack and that the vasospasm in the tissues tends to be relaxed. The drainage rapidly increases as the temperature of the pack is increased to tolerance. The use of the

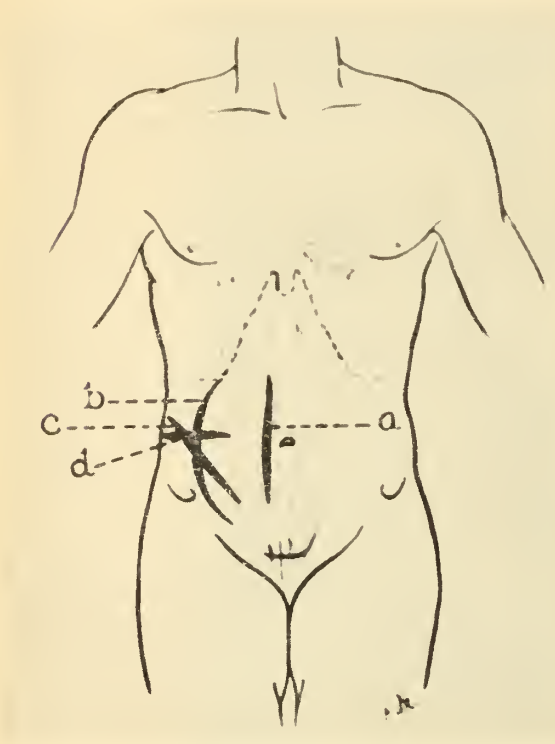

Fig. 4. Incisions commonly used in ligation of the inferior vena cava: *a*, right paramedian, for transperitoneal approach; *b*, *c* and *d*, incisions for extraperitoneal approach.

hot moist pack is of so much value that it should be used as an adjunct in every case (See Instructions).

A ligation, if done, should be of the superficial femoral[14] and this just below its junction with the profunda femoris to form the common femoral (Fig. 3).[1,6,8,9,24,26] This effectively blocks the deep veins of the lower leg and at the same time preserves the collaterals to carry on. The great saphenous vein should be preserved unless it is varicosed. If so, it too should be ligated.

The ligation of the vena cava is a major operation.[27] It can be done through any of four incisions (Fig. 4). Many use the transabdominal. It is best done through the extraperitoneal approach (Fig. 4).[24] Most of this is a muscle-splitting incision with the peritoneum and ureter carried inward. Be very careful of the small veins draining into the vena cava as they can be very annoying if torn. Ligate just above the bifurcation so as to be sure and stay below the left renal vein which at times comes off low. Doubly ligate the vena cava and do not section. If you do, be sure and transfix both stumps.

INSTRUCTIONS FOR HOT PACKS

Must be bed rest. Useless to sit in a chair with the leg resting on another chair, and try to apply hot wet packs.

Body must be lying flat. Only one pillow under head.

Knee should be flexed slightly with the lower leg high on a pile of pillows 16 inches above level of mattress.

Best if the lower leg (knee to foot) is about on the level with the knee slightly flexed.

Packs should be applied at least 10 inches both above and below the area to be treated.

Temperature of packs should be 120 degrees to begin with and then increased as tolerated, preferably to 130 degrees if the patient should not object.

Fresh packs should be applied as quickly as possible at time of change to prevent the cooling of the skin.

The packs are best applied as follows:

1. Fold a blanket four times and place on top of a pile of pillows.
2. Fill the hot water bottles (several, one-half full) with hot water of right temperature. Compress the air out of the bottles as cork is tightened.
3. Wring the large bath towels and wollen blankets out of hot water. Quickly apply the wet towels, then the hot water bottles and then quickly wrap the blanket about it all and pin tightly.

If the above pack is properly applied it will stay hot for at least two hours, and it should all be changed every two hours.

Best results will be obtained if the packs are continued for not less than four hours at a time.

When the ACE bandage is used and applied it is best if the patient walks a great deal.

Pratt[23] states that of 279 major vein resections the past year 21 per cent have been that of the common femoral. In contrast to twenty-six vena caval ligations two years ago, only two were performed the past year. For thrombosis, where vein section was considered imperative, the operation was done bilaterally in only 6 per cent of his cases.

I am so much in favor of the anticoagulant treatment as advocated by Barker[3,4] and so much against the femoral, iliac and vena caval ligations so frequently done that I would like to present a brief summary of Gordon Murray's article. It will convince the most obstinate holdout that the use of the anticoagulants should be the first thought in all these conditions.

Gordon Murray[6] of the Toronto General Hospital, has reported on 400 postoperative patients treated with anticoagulants. None developed thrombosis or pulmonary embolisms.

He further reported on 371 patients with venous thrombosis. All had typical symptoms and

signs of venous thrombosis. None developed pulmonary embolism.

Another group of 149 patients with definite pulmonary embolism were treated by the anticoagulants. These cases were not selected. Fifty-two of them were very seriously ill and in shock when first seen. Even though the statistics show that one in five of all individuals surviving the first pulmonary embolus will die of a later one, no deaths from pulmonary emboli were noted in the entire series where he had control of the dosage and care. No ligations were done in any of these cases.

Conclusions

1. Intravascular thrombosis and clotting can be prevented by the use of the anticoagulants, heparin and dicumarol.

2. If thrombosis and clotting have occurred, anticoagulants in appropriate doses will prevent further extension of the process.

3. If a patient is adequately treated with anticoagulants following pulmonary embolism, the chances of survival are excellent.

THE PAPANICOLAOU METHOD OF CANCER DIAGNOSIS

An Evaluation

KANO IKEDA, M.D.
Saint Paul, Minnesota

AS early as 1923, Papanicolaou, in the course of "a systematic study of human vaginal smears, became aware of the diagnostic potentialities of the vaginal smear in malignant lesion of the uterus." In 1928, he briefly reported these observations. While he continued with the investigation, nothing was again heard from him until 1941, when he and Traut published a paper, "Diagnostic Value of Vaginal Smears in Carcinoma of Uterus." Two years later, their classical monograph entitled "Diagnosis of Uterine Cancer by Vaginal Smear," appeared. This book, copiously and beautifully illustrated, gave, in detail, the method of preparation of the vaginal smear, the classification and identification of various cell types found in the vaginal flora and the description of the exfoliated cancer cells. The Papanicolaou method of cancer diagnosis was thus introduced to the medical profession. In the meantime, a few investigators, notably, Meigs and Ayrs, who early saw a diagnostic possibility in the method, undertook a systematic study of routine vaginal smears in large series of cases, with surprisingly gratifying results. Their enthusiastic reports encouraged clinicians and surgical pathologists, here and there, throughout the country, to follow their lead. Papanicolaou, himself, has conducted a class from time to time, to teach the method and popularize it, which has resulted in the popular acceptance of this method as an aid in cancer diagnosis in qualified hands.

However, many conservative leaders in the field of pathology who direct the minds of the average practicing pathologist, have taken a wait-and-see attitude and have been somewhat hesitant to wholeheartedly endorse the Papanicolaou method of cancer diagnosis as being worthy of adoption in routine work. They seem to view it with the academic interest of a skeptic, rather than with the open and practical mind of a clinical pathologist. They emphasize their preference for the older, more positive and reliable, though less spectacular, biopsy procedure, on the ground that the latter is a tried and established institution, not to be intruded by a seemingly questionable method of diagnosis by cell morphology alone, a practice so long frowned upon by them, as unscientific and inaccurate. They probably see a parallel between it and the interesting observations of MacCarty's on the malignant cell, although the latter was dealing with the individual cells of fresh unfixed tissue. They are apprehensive, too, lest the new technique should replace the biopsy in cancer diagnosis, and thus the universal demand for its use to the practical exclusion of the more reliable histologic method of diagnosis might result. Furthermore, they are fearful lest the cytologists and technicians who are being taught to do the preliminary screening of the smears, might be encouraged to venture into the field of cancer diagnosis. Unfortunately, too, the popular acclaim given the method, through the medium of lay magazines, has tended to discredit its scientific value. The proposition that it might be used as a simple screening test by public health agencies may have caused an unfavorable reaction. Thus, while the pathologist was still biding his time, the clinician, particularly the gynecologist, took the initiative in the investigation and evaluation of the method (for the simple reason that he has a personal interest in his patients) and contributed largely in its development and popularization. The clinician, and not the pathologist, has furnished the leadership in the application of this method in practice, even though it is essentially a laboratory procedure, and the responsibility for the final diagnosis should rest with the pathologist.

The original Papanicolaou method is used to identify various type cells in the smears of the vaginal flora which may contain, in cancer of the uterus, malignant cells exfoliated from the surface layers of the actively proliferating tumor. Several minor modifications have been proposed for preparing and staining the smear, which, however, do not alter its essential features. The accuracy of the method, in experienced hands, has been reported to be in the neighborhood of from 80 to 100 per cent of proven positive cases in large

From the Departments of Pathology, The Charles T. Miller Hospital, Saint Paul, Minnesota and the University of Minnesota, Minneapolis, Minnesota.

series of cases; although a most recent report by a Philadelphia group of investigators gave a 30 per cent failure in sixty-three proven cases of cancer in 500 consecutive gynecologic patients, with 1.6 per cent false positives in the remaining 437 negative patients, a figure which probably more nearly approximates the experience of the average laboratory. More remarkable is the fact that a positive smear has been obtained in early cases of cervical cancer, in a number of instances, in the face of the negative clinical findings. Applied in diagnostic bronchoscopy, it has proven its distinctive value as an early available means of diagnosis, where a biopsy cannot be obtained. Cancer of the urinary tract has also been diagnosed frequently without cystoscopic instrumentation. These are the experiences which cannot be ignored in the final evaluation of the method.

The following illustrative cases are cited from our own experience.

Case 1.—Mrs. R. H., aged thirty-nine, consulted a physician, complaining of excessive and continuous vaginal bleeding for more than a month. Bimanual examination was essentially negative, and the cervix appeared smooth. A routine smear obtained directly from the cervix (a procedure which we prefer to the smear of the vaginal secretion) was positive for cancer cells. On the operating table, the cervix appeared so clean that it was difficult to select a site for biopsy. It was decided not to attempt a rapid diagnosis by frozen section, on a small piece of tissue biopsied, suspecting the presence of the so-called pre-invasive carcinoma *in situ* which could be more convincingly demonstrated by the paraffin section. A vaginal hysterectomy was done immediately thereafter, without waiting for the final confirmatory diagnosis. A histologic examination of the removed uterus revealed a small localized area of retained placenta, accounting for the bleeding; and early epidermoid carcinoma involving a large area of the posterior lip of the cervix in its pre-invasive stage. The biopsied piece from the cervix, however, failed to demonstrate the presence of carcinoma, thus convincingly pointing out the superiority at times of the smear method over the biopsy in this type of cases (carcinoma-in-situ).

Case 2.—Mrs. S. D., aged fifty-five, consulted a physician, complaining of a discharging nipple. On examination, a small amount of grayish-brown secretion could be expressed from the nipple which was smooth and soft. There was no palpable nodule or indurated area in the breast substance. The breasts were symmetrical and identical in appearance and consistency. A smear of the discharge from the nipple revealed many cancer cells which were presumably exfoliated from an intraductal papilloma, probably undergoing malignancy. A simple mastectomy was performed first. The nipple was soft; the main ducts were dilated and filled with a grayish-brown secretion. The breast proper was fatty. Deep within the fatty parenchyma were areas of streaky fibrous proliferation, from which several pinhead comedo specks were expressed, and one small irregular, hard, fleshy nodule about 5 mm. in diameter, which, on frozen section, showed an infiltrating comedo-adenocarcinoma. A radical mastectomy was done. One axillary lymph node showed a metastasis.

Identification of tumor cells in the body fluids, by using various routine staining techniques or their modifications, has long been in practice in the clinical laboratory without attracting any particular interest on the part of the clinician. Papanicolaou's singular contribution to medicine lies in his special staining technique and its application to the vaginal smear in the diagnosis of uterine cancer. It is not difficult to see that the application of the method to the cytological diagnosis of various other body secretions should follow. Thus, cancer cells have been sought and recognized with frequent success in the sputum, bronchial washing, gastric washing, urine, prostatic fluid, as well as the pleural, abdominal and other body fluids. There is, therefore, no longer any doubt that the Papanicolaou method is a valuable adjunct in the practice of cancer diagnosis, not only with reference to the female genital tract, but as applied to any exfoliated cells derived from any tumor in any organs of the body.

Because of the relative simplicity of obtaining the smear, and the low cost of the procedure, coupled with the many encouraging reports already published, the Papanicolaou method will undoubtedly become increasingly popular among clinicians, and might be too freely substituted for the usual biopsy. Therein lies the real danger, against which the medical profession and the public should be warned, for the limitations inherent in it, freely acknowledged by all investigators, are likely to be ignored by the enthusiasm of the less informed.

It should be emphasized also that the success of the method depends, in a large measure, upon the close co-operation between the clinician and the pathologist in every detail of the execution of its procedure and the final interpretation of the smear.

The method should not be used as a final and sole means of cancer diagnosis. On this point Papanicolaou himself states that "the smear technique should not be considered as a substitute for biopsy, curettage, or any other standard

method of diagnosis, but as an adjunct to them. Its greatest value is that it permits recognition of malignant neoplasms at a relatively early stage and in instances in which other diagnostic methods may fail. This point has been fairly conclusively proven by us and other investigators." Meigs, who pioneered in the investigation of this method, says, "Vaginal smear and biopsy are complimentary techniques which, used together, will enhance the effectiveness of the diagnostic clinic. The most important contribution of the vaginal smear technique may be in cancer control. A large number of women may be screened and those with positive smears studied further by biopsy. We do not regard a negative smear as excluding cancer; nor do we regard a positive smear without biopsy corroboration as an indication for surgery."

Briefly enumerated, the Papanicolaou method offers these advantages over biopsy: (1) the simplicity of obtaining the smear*; (2) the low cost of the procedure; (3) a better nuclear stain than that obtained by the conventional hemotoxylin and eosin method; (4) the adaptability to pre-clinical cases and cases beyond the reach of biopsy; (5) the routine use in the follow-up in cases of cancer of the uterus, under radiation therapy; (6) the adaptability to routine gynecological office practice and the use in the cancer control and similar clinics (with its limitations fully appreciated); (7) the smear may be repeated as often as necessary. Against these, the following disadvantages may be cited: (1) the staining technique is more time-consuming than the conventional frozen section procedure and cannot be adopted in the rapid operating room diagnosis; (2) the satisfactory examination of a smear may be too time consuming for the busy pathologist; (3) the histologic pattern of the tumor often essential in cancer diagnosis cannot be obtained; (4) the danger of depending on the cytology of single exfoliated cells cannot be altogether eliminated; (5) the cytologic appearance may be misleading and offer little help in distinguishing the type of a malignant tumor; (6) an element of chance and the personal equation may sometimes influence the interpretation and final diagnosis in the less experienced; (7) a sense of false security in a negative report, often in the presence of a lesion, cannot be entirely eliminated.

*Proper fixation of the smear, namely, to fix it in alcohol-ether, WHILE WET, is absolutely essential.

Thus, these two methods of cancer diagnosis, the cytological (the Papanicolaou technique) and the histological (the biopsy) may be regarded as two distinct and fundamentally different approaches to a common objective. Yet, they are not to be considered as two major rival procedures but only as complimentary techniques, each with its advantages and disadvantages, the former never to replace or substitute for the latter, which should maintain its preferred place in laboratory diagnosis of tumors.

Finally, it may be stated that Papanicolaou, himself, is extremely modest in his claim for the technique, and freely admits that some other staining method may prove to be superior in the experience of others. He confesses his own inability to identify questionable cells by his technique, and declares that ten false negatives are better than one wrong positive diagnosis. He emphasizes that his method should never replace or substitute for the biopsy. On the contrary, he insists on biopsy confirmation. He recognizes the cumbersomeness of his technique and hopes to simplify it. He does claim that his nuclear stain is clearer and sharper, and the cornifying cancer cells are more distinctly brought out on the smear (particularly in epidermoid cancer of the lung) by his technique than by any other method now in use. He believes that the Papanicolaou method of cyto-diagnosis of cancer has come to stay and will enjoy a peculiarly useful place in cancer diagnosis. He further believes that it will eventually be accepted as a laboratory procedure entrusted in the hands of the pathologist Up to the present, however, he has given instruction in the cytologic diagnosis of cancer and his own staining technique to selected groups of clinicians and technicians, as well as pathologists, all of whom appear to have come away favorably impressed.

There may be an inherent danger of permitting the lay cytologists and technicians to wander too deep into the realm of cancer diagnosis. Just how to control this situation cannot be readily answered. It may be pointed out, however, that the recognition, if not the diagnosis, of a leukemic state through the blood smear by trained hematological technicians is being tolerated. Similarly, the identification of abnormal cells by this method by trained technicians under the supervision of a pathologist, who should make the final diagnosis, may be accepted. The grave danger of office diagnosis by clinicians without special training or by

EXPERIENCE WITH SCREENING TESTS IN THE DETECTION OF CANCER

DAVID STATE, M.D.
Director, Cancer Detection Center, University of Minnesota
Minneapolis, Minnesota

CARDIOVASCULAR disease and cancer are the two greatest causes of death in this country. Of all malignancies, malignancies of the internal organs present the most acute problems, because they are silent for such a long period of time. Particularly is this true of cancer of the stomach and cancer of the large bowel, which together cause more deaths in both sexes than all other forms of cancer combined. Additionally, we are faced with the problem that the population of the United States is growing older so that by 1980, 40 per cent of the population will be over forty-five. The incidence of carcinoma will undoubtedly increase as the number of people in the older age groups is augmented.

The over-all picture for the results of surgery and treatment of malignancies is definitely influenced by the stage in which the disease is attacked. If the lesions are confined to the organ without the presence of metastases, the outlook is excellent. For example, in carcinoma of the stomach where the tumor is confined to the organ, a five-year cure reaches 60 per cent whereas the five-year survivals after metastases have occurred in about 6 per cent. There can be no question, then, that the ultimate hope for a better outlook in the problem of therapy in cancer rests with early diagnosis of the malignant lesion.

Unfortunately, cancer in its early stages is silent, and for that reason tests and examinations must be carried out upon individuals who seem to be apparently well. At the University of Minnesota two such studies have been undertaken within recent years. First, a study was started in the spring of 1945 in an effort to determine gastric cancer in individuals who had no symptoms. Since achlorhydria occurs in approximately 70 per cent of all patients with gastric carcinoma and an additional 15 or 20 per cent have hypochlorhydria, it was felt that examination of individuals who have achlorhydria and hypochlorhydria could possibly lead to the uncovering of silent gastric cancers. Histamine hydrochloride in triple doses of 0.5 mgm. each at half-hour intervals were given subcutaneously as a gastric acid stimulant. All individuals over the age of fifty who registered at the out-patient department at the University Hospital, were subjected to gastric expression following histamine stimulation. Free acid was tested for with Topfer's reagents, and quantitive estimations were made using 0.1 normal NaOH and Topfer's reagent and phenophthalein as indicators. Those individuals having achlorhydria and hypochlorhydria then had x-ray examinations of the stomach. The roentgenographic examination consisted of a fluoroscopic examination with an appropriate number of routine and spot films when indicated. In a number of instances, the patients for one reason or another were not given the three doses of histamine, and accordingly these patients have been dealt with as a separate group, the number of histamine injections given being indicated in those patients found to be achlorhydric. If no gastric lesion was found, each achlorhydric patient was given an appointment slip for re-examination in six months. In addition to achlorhydric and hypochloric groups, individuals with gastric polyps and pernicious anemia were also examined in a similar fashion. From a previous study by Dr. Wetherby of our institution, it was possible to obtain a series of patients who had been tested for histamine achlorhydria in 1940. These patients were recalled, and repeat examinations of the gastric juice and roentgenograms of their stomachs were done. In an effort to widen the scope of the project, so as to bring under observation more people who possibly could harbor the disease, individuals who had a family history of gastric carcinoma were included, and, in addition, people who had occult blood in the stool (Guaiac) and unexplained hemoglobin value of 11.0 grams or less (Sahli) were also examined.

Observations

From August 1, 1945, to May 1, 1948, inclusive (Table I), 2,977 patients who passed through the out-patient department at the University of Minnesota were eligible for this precursor gastric

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 8, 1948.

cancer study. Of this group, 2,890 had gastric expressions and 460 were found to be achlorhydric to triple histamine, 212 were achlorhydric to double histamine, 239 were achlorhydric to a hypochlorhydria, ten gastric carcinomas were present. In 110 patients of Dr. Wetherby's list, 113 gastrointestinal x-rays were obtained, and six polyps were found. Of seventy patients with

* Two additional cases missed through organizational errors, and one additional case missed by x-ray and uncovered at operation for unrelated condition.
** One polyp found at post-mortem, two additional polyps found at gastroscopy and missed by x-ray.

single dose of histamine, and an additional ninety had hypochlorhydria, that is, less than 30 degrees of free acid. In these groups 719 gastrointestinal x-rays were taken in the individuals with achlorhydria to triple histamine, 254 in achlorhydria to double histamine, 195 in the individuals who were achlorhydric to a single dose of histamine, and finally, fifty-two were obtained in individuals who had hypochlorhydria. In all, then (Table II), 1,168 gastrointestinal x-rays were obtained in 911 patients with achlorhydria, and an additional fifty-two were obtained in the ninety individuals with hypochlorhydria. In these groups of patients, nineteen gastric polyps were found, with an additional thirteen questionably present, and seven silent gastric carcinomas were uncovered. Early in the study, two conditional cases were missed through errors in organization of the project and one additional case was missed by the x-ray examination; this was uncovered at a later date at operation for another unrelated condition. Thus, in all these patients with achlorhydria and pernicious anemia, twenty-six new and forty-four old, 136 gastrointestinal x-rays were taken. Four gastric polyps were found and two silent gastric carcinomas. Three polyps in the patients with pernicious anemia were found by gastroscopy. These were overlooked in the roentgenogram. One additional polyp was found at autopsy examination. In the sixty-seven patients who were relatives of individuals who had gastric carcinoma, sixty-seven x-rays were obtained, and no polyps or cancers were found. In patients with a hemoglobin of 11.0 grams or less, forty-five x-rays were obtained for forty-five individuals, and no polyps or gastric carcinomas were noted. Eighty-seven patients with occult blood in the stool had seventy-five x-rays, and no unusual findings were noted from the standpoint of the presence of gastric pathologic lesions. All in all, 1,380 patients had 1,656 gastrointestinal x-rays, and twenty-nine gastric polyps and nine gastric carcinomas were found.

The need for developing some workable plan

that will filter out those individuals most likely to harbor a gastric malignancy is substantiated by the studies of St. John, Swenson and Harvey in 1944 and of Daily and Miller in 1945. From

TABLE III. RESULTS OF PRECURSOR GASTRIC CANCER STUDIES

Investigators	Number Receiving GI Studies	Findings
St. John, Swenson and Harvey (1944)	2,413 over the age of 50 without gastric complaints	2 carcinomas 1 lymphosarcoma
Daily and Miller (1945)	500 males over 45 presumably free of digestive complaints	1 benign gastric ulcer 1 polyp 1 antral gastritis
Univ. of Minnesota (1945—1948)	Over the age of 50 1,111 free of digestive complaints with histamine achlorhydria and hypochlorhydria	7 gastric cancers 25 gastric polyps

Table III, it can be seen that the former group subjected 2,413 patients over the age of fifty without gastric complaints to a brief fluoroscopic examination after ingestion of barium and found two silent gastric carcinomas and one lymphosarcoma, an incidence of unsuspected gastric malignancy of 1.2 per thousand patients. No gastric polyps were uncovered in this group. Daily and Miller reported on a series of 500 patients subjected to barium examination of the stomach. These examinations were performed on presumably normal men over the age of forty-five free of digestive complaints. Three gastric lesions were found, a benign gastric ulcer, a polyp, and antral gastritis in a third patient. It can thus be seen that employing the above-described filters, particularly achlorhydria, hypochlorhydria and pernicious anemia, as precursor gastric carcinoma groups, has permitted the discovery of a greater number of gastric malignancies for a given number of x-ray examinations of the stomach than in the studies described above.

Perhaps the most fruitful result of our investigation has been the uncovering of twenty-nine gastric polyps. Although many authors (Borrmann, Schindler, Rigler) have considered polyps of the stomach precancerous lesions, their actual status is difficult to evaluate in any given instance, as Spriggs and Marxer have indicated. It is one of the purposes of this study to attempt to secure a more satisfactory answer to the question of whether or not gastric polyps become malignant. This phase of the study has been carried out by Dr. L. Hay of our department, and we have noted in the gastric polyps under our observation that three have shown evidence of conversion of benignity to malignancy.

Cancer Detection Centers

As a result of the efforts employed in the precursor gastric cancer study as described above, it is felt that it would be more profitable to examine individuals as a whole rather than concentrating on any particular organ of the body. The thesis of the Cancer Detection Center has been the same as for the gastric precursor group namely, that cancer in its early stage is a silent disease, and to improve the end results of cancer therapy the lesions must be attacked in the early stages of development. With the approval of the Minnesota State Medical Association, the Cancer Detection Center has been set up as a clinical experimental project whose prime purpose is to examine apparently well individuals over the age of forty-five for the presence of symptomless malignancies. This clinical project will have a limitation of five years, after which the results will be carefully evaluated to determine its value. It is anticipated that only 1,000 patients will be examined each year, so that at the end of five years, 5,000 new patients will be examined. All patients will have re-examinations at six-month intervals. The emphasis in the Cancer Detection Center is on complete and thorough examination of a few, rather than relatively superficial examinations of large numbers of individuals. The examination, as carried out, takes one complete day, and the following parts of the examination are done in the morning:

(a) Complete blood count.
(b) Urinalysis.
(c) Blood Wassermann test.
(d) Occult blood in the stool (both by Guaiac and Benzidine tests).
(e) Gastric expression, using histamine as a gastric acid stimulant.
(f) A proctoscopic examination by a proctologist.

(g) Female patients have complete pelvic examination by a gynecologist.

As yet, the Papanicolaou technique is not being used routinely, but it is anticipated in the near future that this technique will also be added. Finally, before the morning examination is completed, the individual has an examination of the chest by means of the photofluorogram which is taken in both inspiration and expiration. The individual is then permitted to have lunch and returns in the afternoon for a complete physical examination by one of our doctors, using a routine examination form which has as its prime purpose the early detection of precancerous lesions as well as early carcinomas. We have recently added to our staff an otolaryngologist who examines the ear, nose and throat as well as the larynx of all patients, because it is our feeling that this is one area of the body which may harbor carcinoma without symptoms for a long period of time. You will note that routine examinations of the gastrointestinal tract and large bowel are not made because we are endeavoring to introduce workable filters here at the Cancer Detection Center, as well as in the gastric precursor study. To this end, then, the following individuals receive gastrointestinal x-ray series:

(a) Individuals with histamine achlorhydria and hypochlorhydria (less than 30 degrees freed acid).
(b) Patients with occult blood in the stool.
(c) Patients with a strong family history of gastric carcinoma.
(d) Patients with unexplained hemoglobin level below 11.0 grams.
(e) Patients with vague symptoms of gastric pathology which in any sense could be interpreted as being due to gastric carcinoma by the examining physician.

Similarly, the following individuals are given barium enemas:

(a) Patients with abnormal findings on proctoscopic examination.
(b) Patients with occult blood in the stool.
(c) Patients with unexplained hemoglobin level below 11.0 grams.
(d) Patients with a family history of large bowel malignancy.
(e) Patients who have vague symptoms that could possibly be conceived as being due to malignancy of the large bowel by the examining physician.

These examinations are not given on the day of the original visit to the Cancer Detection Center, but provisions are made for examinations by our x-ray department at a convenient later date.

At the completion of the examination the results of such examinations are discussed with the patient carefully and fully and in as nontechnical terms as is possible and then the individual is told to return to his family physician where he may obtain further information of a more detailed nature. Similarly, if any cancer or precancerous lesion is found, the patient is told to return to his personal physician so therapy may be instituted directly. A detailed analysis of our results, both positive and negative findings, is sent to the personal physician so that he may be fully aware of our findings. Individuals come to us, either by referral from their personal physician or of their own free will. If they come to us direct, they must give the name of some physician who is approved by the State Medical Association to whom we report our findings.

Examination being completed, the individual is then given a reappointment for a six-month checkup, at which time a complete examination, the nature of which has been described above, is performed.

Because of delay in obtaining even a temporary building, the Cancer Detection Center did not open its doors for examination of individuals until March 1, 1948. The response on the part of the public to this project has been almost overwhelming. To date approximately 8,000 individuals have applied for examination, but since our facilities are limited, we are at present not making appointment for examination more than six months in advance. In the meantime, we encourage all individuals to see their own personal physician so that a thorough examination can be carried out. From Table IV, it can be seen that 281 individuals have been examined at the Cancer Detection Center from March 1 to April 30, 1948, inclusive. In this group, five silent cancers have been found, three of these in the large bowel and two basal cell carcinomas of the skin of the face. In the first two weeks of the month of May,

TABLE IV. SUMMARY OF FINDINGS OF THE CANCER DETECTION CENTER, UNIVERSITY OF MINNESOTA

March 1, to April 30, 1948, Inclusive

I.	Total number of patients examined	281
II.	Carcinomas—total number	5
	Cancer of rectum	2
	Cancer of the cecum	1
	Basal cell carcinomas of face	2
III.	Precancerous lesions—total number	70
	Rectal polyps (including adenoma)	38
	Keratosis of skin	10
	Pigmented neavi in areas of irritation	11
	Kraurosis vulvae	2
	Oral leukoplakia	4
	Solitary thyroid adenoma	4
	Gastric polyposis	1
IV.	Benign Tumors—total number	40
	Adenocyatic disease of breast	1
	Hemangioma	2
	Fibroma	1
	Lipoma	2
	Sebaceous cyst	6
	Polyps of cervix uteri	11
	Pyogenic granuloma	1
	Cysts of cervix uteri	3
	Myomata of uterus	4
	Thyroglossal duct cyst	1
	Papilloma of skin	2
	Adenoma of prostate	3
	Urethral caruncle	3
V.	Suspicious tumors requiring further diagnostic procedures—total	16
	Tumors of lip	4
	Tumor of tonsillar pillar	2
	Tumor of tongue	1
	Adenal masses	6
	Uterine masses	1
	Ulcer of cervix	1
	Cervical erosion	1
VI.	Non-cancerous conditions requiring medical attention—total number	61
	Duodenal ulcer	4
	Cholelithiasis	1
	Arteriosclerotic heart disease	17
	Hemorrhoids	20
	Varicose veins of lower extremities	5
	Perforated ear drum	3
	Hepatomegaly	2
	Anal fissure	1
	Cataracts	2
	Chronic cervicitis	1
	Hydrocele	2
	Arthritis	1
	Calcifying myositis	1
	Hernia (inguinal)	1

The above findings noted in 134 of the 281 patients examined.

TABLE V. SUMMARY OF LABORATORY FINDINGS OF THE CANCER DETECTION CENTER, UNIVERSITY OF MINNESOTA

March 1, to April 30, 1948, Inclusive

I.	Stools for Occult Blood—total number	281
	Benzidine positive	26
	Guaiac trace	9
	Guaiac positive	7
	Total	42
II.	Urinalysis—total number	281
	Positive for sugar	10
	Positive for albumin	5
	Total	15
III.	Blood counts—total number	281
	Hemoglobin level below 11.0 grams	5
IV.	Gastric expression—total number	276
	Achlorhydria (after histamine)	45
	Achlorhydria (no histamine)	5
	Hypochlorhydria (after histamine)	39
	Hypochlorhydria (no histamine)	4
	Hyperchlorhydria	1
	Total	94

three additional carcinomas were found, all in the large bowel. To May 15, for the first two and a half months for which figures are available, eight carcinomas have been uncovered, and seventy precancerous lesions have been detected. Chief amongst these have been rectal polyps including adenomas, of which there have been thirty-eight. Ten individuals had keratosis of the skin, eleven had pigmented naevi in areas of irritation, in two there was kraurosis vulvae, in four leukoplakia (oral), in four solitary thyroid adenomas, and in one gastric polyposis. There were forty instances of benign tumors, and sixty-one instances in which noncancerous conditions requiring medical attention were uncovered, chief among which were arteriosclerotic heart disease and hemorrhoids.

The above findings were noted in 134 of the 281 patients examined. It can thus be seen that the early results of our studies at the Cancer Detection Center have been most encouraging. Although the effort is great, and the time spent considerable, still if the results continue to be as fruitful as they have in the first two and a half months, there can be no question that this project is a worth-while one.

CANCER IN MINNESOTA CHILDREN

D. S. FLEMING, M.D., M.P.H., and N. O. PEARCE, M.D.
Minneapolis, Minnesota

IT HAS long been recognized that many children die of cancer. It is doubtful, however, whether physicians in general are aware of the fact that cancer is now among the leading causes of death in Minnesota children under fifteen years of age. If we exclude congenital malformations, diseases peculiar to the first year of life, and accidents, cancer (or leukemia) has ranked among the first five causes of death in children from birth through age fourteen in Minnesota during the years 1944 to 1947.*

The five leading causes of death for Minnesota children for the years indicated, with the exceptions noted, were as follows:

1944	1945
1....Pneumonia	1....Pneumonia
2....Diarrhea and enteritis	2....Diarrhea and enteritis
3....Measles	3....Influenza
4....Influenza	4....CANCER (32 deaths)
5....CANCER	5....Heart disease (32 deaths)
1946	**1947**
1....Pneumonia	1....Pneumonia
2....Poliomyelitis	2....Diarrhea and enteritis
3....Diarrhea and enteritis	3....LEUKEMIA
4....CANCER	4....Diseases of the nervous system
5....Influenza	5....Whooping cough

As Dr. Harold W. Dargeon recently pointed out, the high rate of mortality from cancer among children "is probably mainly due to the decline in deaths from other diseases. Increasing recognition and more accurate diagnosis have likewise raised the statistical incidence."[1] Since cancer does rank so high as a cause of death in children today, the subject calls for much more thorough study than it has hitherto received.

Considerable data on cancer among children have been gathered in a survey of all cancer deaths reported by Minnesota hospitals since 1940. This survey has been carried on by the Division of Cancer Control of the Minnesota Department of Health. Table I shows the number of deaths from cancer among Minnesota children under fifteen years of age for the years 1940-1947 inclusive. Table II shows the deaths among children of similar age from lymphatic leukemia, myelogenous leukemia, and Hodgkin's disease.

It will be seen from these tables and the accompanying graph that both cancer and leukemia may attack children at a very early age. Indeed, it is during the first five years that the largest number of deaths occur from both cancer and leukemia. The age curves for both types of disease show a tendency to dip during the age period five to eleven years, with a slight rising tendency in the early teen ages. In the children included in this study, the sharp rise in leukemia deaths at age two is particularly striking. It seems probable that many cases of leukemia that caused death at two years of age were present at birth and reached the fatal stage some time during the second year of life.

There is a notable sex difference in the cancers occuring in this group of children. As Table I shows, four cancers were found in boys to every three in girls. The leukemias do not show so marked a sex difference, although there are more cases of both types of leukemia in boys than in girls. The total number of cases of Hodgkin's disease is so small that the sex difference may be insignificant.

Table I also indicates the great variety of primary sites at which cancer has occurred in Minnesota children in recent years. The largest number have been found in the brain and nervous system. The kidneys, bones, and abdomen also rank high as primary sites.

It is of interest to note that in the larger series reported by Dr. Dargeon and his associates from the Children's Tumor Registry and Pediatric Service, Memorial Hospital, New York, the six main body areas in which cancer was reported were the central nervous system, bones, eye, kidney, blood and lymphoid system, and skin and supporting tissues. Also in that series of cases, the mortality incidence from both cancer and

Dr. Fleming is Chief, Section of Preventable Diseases and Dr. Pearce is Acting Director, Division of Cancer Control of the Minnesota Department of Health.

*For the period 1944-47 inclusive, exact figures are not available on the total population for the age groups considered. Census figures for 1940 give the following data for Minnesota children:
0-5 years: males, 140,327; females, 133,638
6-14 years: males: 211,622; females, 203,444
Estimates for 1946 indicate a decrease of 3.5 per cent for the entire population under 21 years of age. Therefore the estimated total population for these age groups, averaged for 1944-47, would be as follows:
0-5 years: males, 135,415; females, 128,960
6-14 years: males, 204,214; females, 196,323
These figures indicate that there are considerably more children in the 6-14 year age group than in the 0-5 year age group. The figures indicate no significant sex distribution.

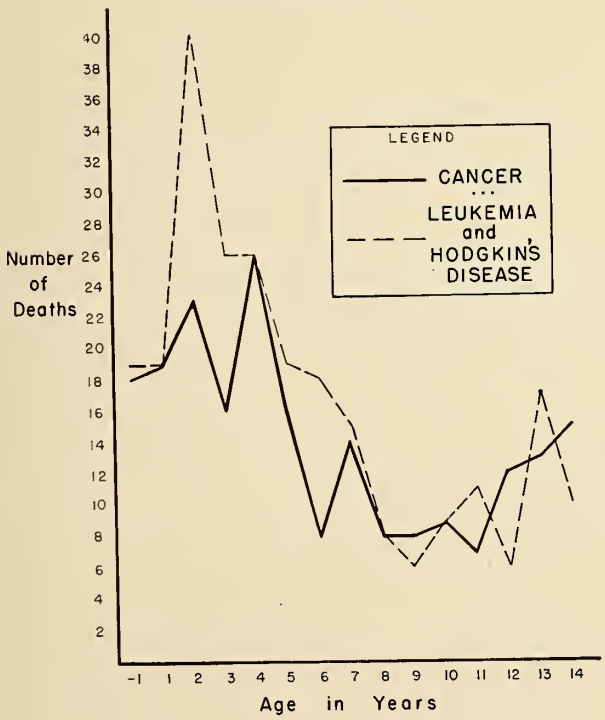

TABLE I. NUMBER OF DEATHS FROM CANCER AMONG CHILDREN RESIDING IN MINNESOTA
1940-1947 Inclusive

Primary Site of Cancer	Age of Children in Years														Total Deaths, Birth to Age 14	Sex of Child

DEATHS FROM CANCER, LEUKEMIA, AND HODGKIN'S DISEASE AMONG MINNESOTA CHILDREN, FROM BIRTH TO FOURTEEN YEARS OF AGE.
1940-47 Inclusive

Graph 1

COMPARATIVE NUMBER OF DEATHS FROM CANCER AND FROM LEUKEMIA AND HODGKIN'S DISEASE IN MINNESOTA CHILDREN IN TWO AGE GROUPS.

Graph 2

leukemia was highest in children from birth to four years of age. Deaths from leukemia for that early period totalled more than those for the succeeding ten years, and deaths from cancers and other tumors during the first four years of life numbered 3,095, as compared with a total of 3,958 for the succeeding ten years.[2]

Cancers of the brain and nervous system appear to be fairly well distributed through the entire age range in the Minnesota children with a possible, though by no means certain, decrease after age eight. Cancers of the kidney and liver are fairly well concentrated in the lower age ranges. Bone cancers show rather more of a tendency to prove fatal during the later ages of childhood. A few abdominal cancers were found in this group of Minnesota children at nearly every age.

Lymphatic leukemia dropped fairly consistently from age four to age thirteen, but myelogenous leukemia showed only very slight variations with age. In Hodgkin's disease, as stated above, the cases are too few to indicate any sort of trend.

Because cancer and leukemia are so prevalent in children, it is obvious that physicians examining children should be constantly on the alert for symptoms that may be indications of these diseases, particularly since they are known to progress rapidly during childhood. A number of the cancers in this series were discovered only on autopsy. Special diligence is required in looking for signs of cancer in infants and preschool children. This group of Minnesota children, from birth to five years of age, contributed more deaths, 118, than did all the children in the much larger age group, six to fourteen years, in which 100 cancer deaths occurred. The same relationship holds for the leukemias and Hodgkin's disease. Among children five years of age or younger, deaths from these causes totalled 149; in children six to fourteen years of age, deaths totalled only 100.

As Dr. Dargeon reminds us, "A disorder that appears to satisfy all but a few of the criteria of a common disease may be cancer. . . . Repeated investigation, therefore, should be routine in the presence of (a) an atypical symptom complex or (b) an unusual child patient. . . . The child who is a behavior problem may likewise have a neoplasm."[1]

THE PAPANICOLAOU METHOD OF CANCER DIAGNOSIS

(Continued from Page 56)

technicians, and this should be repeatedly pointed out, lies in the fact that the method, in some respect, is found to be more involved than the biopsy, and the incidence of error in such hands would necessarily be far too great. Yet, this seems to be the trend. Since the pathologist, in a sense, is regarded as the final word in cancer diagnosis, it is reasonable to expect that he should take cognizance of the involved situation and offer his assistance in the solution of the problems arising from the universal practice of this useful, yet dangerous method. To that end, he should take advantage of every opportunity to be enlightened on the subject and urge the future pathologists to include in their training a course in cyto-diagnosis. Fellowships in cyto-diagnosis of cancer, such as those sponsored by the American Cancer Society, should be regarded as an answer to the present need.

Conclusions

The Papanicolaou cytologic method should be recognized as a laboratory procedure in cancer diagnosis. It must be considered as an adjunct to, and not a substitute for, the biopsy. When frankly positive (Papanicolaou's Class V), it is as conclusive as a histologic section. The rule should be, however, that a positive smear should be corroborated by the biopsy or the clinical evidence. A negative result should never be accepted as final. The fact that it depends solely upon the cytology of the exfoliated cells, and a personal factor may sometimes play a part in the interpretation and diagnosis, makes the method dangerous, unless employed with the full appreciation of its limitations. On the other hand, the fact that it has been proven to give a positive diagnosis in preclinical lesions and in lesions beyond the reach of the biopsy makes it a doubly welcome addition to the available methods of cancer diagnosis; yet this should not alter its fundamental shortcomings and evoke undue enthusiasm for, or reliance upon, it. The vaginal smear method may be employed as a routine measure in gynecological office practice or in a mass survey of women in a clinic or a cancer detection center as a preliminary screening process, only where proper and

THE CANCER PROBLEM FROM THE STANDPOINT OF THE PRACTICING PHYSICIAN IN THE SMALL COMMUNITY

DAVID P. ANDERSON, M.D.
Austin, Minnesota

THE INCREASING pressure of public opinion makes it mandatory that the practicing physician, particularly the physician in a smaller community, evaluate his own abilities and shortcomings in the diagnosis and treatment of cancer. The larger medical centers are able to point with justifiable pride to statistical improvement in the treatment of various types of cancer; lay groups are waging enthusiastic educational campaigns designed to bring the patient to the physician in the early stages of the disease; cancer detection centers are being established in many localities; and cancer research is receiving better support. Thus far, however, too little attention has been directed toward the position of the independent practicing physician in relation to the cancer problem. Yet he is the key to the reduction of cancer mortality, at least until some universal diagnostic test or cure for cancer is determined, for he is the one who has the best opportunity to discover cancer in its early stages.

Is the practicing physician at fault in the delay in the diagnosis of cancer? Apparently the answer is "Yes." Leach and Robbins,[1] in a very revealing recent survey, determined that the physician alone is responsible for the delay in the diagnosis of cancer (all types) in 27.8 per cent of the cases studied. The physician's culpability rises to almost 50 per cent in internally located cancer. A survey of seventy-two new cases of cancer in sixty-eight patients, seen by the author in his practice over a period of slightly more than two years, is shown in Table I and compared with the report of Leach and Robbins. The criteria established by Leach and Robbins were used in the analysis of these cases.

These seventy-two cases were either seen directly by the author or referred to him by some fourteen different physicians in the community. Cases in which the primary diagnosis was made elsewhere are not included. This series, though small and perhaps not statistically significant, does indicate that there is still a tremendous chance for improvement in the early diagnosis of cancer even in a comparatively small community where the physician-patient relationship is more intimate than in larger centers.

TABLE I. DELAY AND CULPABILITY IN CANCER DIAGNOSIS

	Leach& Robbins	Present Study
Patient alone	32.0%	37.5%
Patient and Physician	10.8%	2.8%
Physician alone	27.8%	16.7%
No delay	29.4%	43.0%

Why does the average practicing physician, who is almost always the first physician to see the patient, too often fail to fulfill his obligations to detect cancer in its early stages? There are many intangible aspects to the answer to this question, but some rather obvious reasons for delay in the diagnosis of cancer are apparent to those of us who form a part of that large group of average practicing physicians. In the first place, the "average" must always be considered, and in so doing, the sins of a few are laid at the feet of many. Lack of education, in a specific sense, is not the major fault that many believe it to be. However, the mental stimulation and constant re-education that is more or less forced upon a man associated with a teaching institution is either not available to, or not forced upon, the large group of independent practicing physicians, particularly those in smaller communities. Education or re-education of the practicing physicians therefore becomes a major weapon for the profession in combating delay in the diagnosis of cancer. Post-graduate refresher courses and clinics, such as are easily available in Minnesota, are of unquestioned value in this re-education process. Unfortunately, however, it is usually the better-than-average practicing physician who avails himself of such benefits. An intensive educational program, enticing enough to attract all physicians and conducted through the component county medical societies, might better serve to reach a larger group of physicians. In sharp contradistinction to the usual course of events, the smaller and more isolated the society, the better should be the program. (The Cancer Education Service of the Cancer Committee of the Minnesota State Medical Association, operated in co-operation with the Cancer Control Division of the Minne-

sota Department of Health, is designed to answer this problem in Minnesota).

The extreme pressure and the very nature of his everyday practice is another major factor in causing the average practicing physician to delay too long in the diagnosis of cancer. Certainly he knows, for example, that cancer of the stomach must be diagnosed early if there is to be any hope at all of cure; and he is equally cognizant of the fact that an x-ray examination is his best aid in establishing such a diagnosis. However, the busy physician sees hundreds of patients with vague, ill-defined and usually minor gastric complaints before he encounters one cancer of the stomach. He cannot x-ray all of these people, although it might be the ideal procedure, nor can he refer even a major portion of them to a specialist, or else he would not long remain in practice. What is the answer then to his dilemma? How can he sort out the early malignant disease, which when early is protean and mild in its manifestations, from the multitude of lesser ills? The better-than-average busy physician has usually solved this problem satisfactorily in a manner which we will stress later.

A third factor which tends to lessen the sensitivity of the average physician in the matter of cancer diagnosis is a general lack of enthusiasm, often more real than apparent on the surface. This is occasioned by a number of factors. Cases which he does diagnose early are referred to a surgeon or radiologist or a group of specialists who are accordingly given credit for the cure. The late incurable cases are quickly referred back to the general practitioner after a palliative procedure has been performed. He spends many days and nights with these patients answering the questions that have been left unanswered, dressing the wound that is still draining, controlling pain, and, finally, signing the death certificate. When such cases constitute the bulk of his experience with cancer treatment, it is no wonder that his enthusiasm is dulled! Perhaps a local cancer clinic at regular intervals, based on a survey of cancer cases diagnosed or treated at the local community hospital, would serve as a stimulus for practicing physicians in small communities. A surprisingly large volume of clinical material, which would be of personal interest to the local physicians, would thereby become available for a physicians' educational program.

There are many practical methods to aid in the shortening of the lag period in the diagnosis of cancer that are discussed today, aside from the hope that intensive cancer research may sooner or later offer a universal diagnostic procedure for the detection of cancer. Education of the public, cancer detection clinics, and education of practicing physicians have all been stressed as means of reducing the lag period in the diagnosis of cancer, and thereby reducing the mortality of this disease. The value of cancer detection clinics and public education is unquestioned, but in our opinion the final responsibility for the early detection of cancer falls directly upon the shoulders of the practicing physician. It is our belief that the major effort to shorten the lag period in the diagnosis of cancer must be directed towards the well-established personal physician-patient relationship.

Leach and Robbins have forcefully stressed the role of the practicing physician in cancer mortality reduction as follows: "The hope of making appreciable immediate reduction in cancer mortality lies with the individual physicians. The cancer clinic can reach but relatively few persons. The physician, whether he be general practitioner or specialist, internist or surgeon, must operate his own cancer detection clinic in his office and in his hospital service, before any reduction in cancer mortality is made. The means for reducing morbidity and mortality due to cancer are at hand. They remain to be used."

We would add to the need for education of the individual physician a plea for better organization among practicing physicians, particularly those in smaller communities. In larger cities and medical centers, the ready availability of various specialists and of tumor clinics should preclude the need for pooling of equipment and abilities. However, in smaller communities and rural districts where the majority, if not all, of the practicing physicians are general practitioners, we believe that there is a definite need for an informal organization of the practicing physicians in order to improve cancer morbidity and mortality. Such organization simply implies a more general use of existing facilities and individual abilities, and a cohesive effort on the part of the group to improve diagnostic facilities, preferably through a common medium such as the community hospital. No formal organization is necessary except the existing local medical societies, but the group effort must be strong

enough to transcend individual petty jealousies. It need not interfere with the individual practice of medicine, but should, in fact, strengthen the position of the private practitioner by improving his cancer morbidity and mortality rate and generally raising the standards of medical practice in the community. We are firmly convinced that the public now expects the individual physician to produce results commensurate with the generally improved results of cancer diagnosis and treatment in specialized centers. The pressure of public opinion is a powerful force that cannot long be ignored even by such individualists as physicians in our smaller communities.

The individual physician's evaluation of the facilities available to him in the diagnosis and treatment of cancer will logically proceed under the following general headings:

1. *Physical Examination.*—It may seem trite to review the individual physician's ability to perform a proper examination, but continued reiteration of the necessity for a careful physical examination in the detection of cancer cannot be overemphasized. "More is missed in medicine by not looking than by not knowing." It is significant that Leach and Robbins, in discussing the survey previously quoted, said, "In over 80 per cent of the patients in this study, the diagnosis of cancer could have been suspected or made by the initial physician if only a careful history and physical examination had been made."

We believe that the better-than-average practicing physician is seldom guilty of overlooking or not suspecting the presence of cancer chiefly because he will not allow himself to perform a poor examination. If, in spite of a busy practice, the physician takes a careful history of the case he will usually be able to segregate the more serious ailment from the multitude of lesser ills. It has been said, "If you listen to the patient long enough, he will tell you the diagnosis." However, if the diagnosis is not clear after a careful history and physical examination, the physician must insist on a more careful study of the case and make it clear to the patient that he must return for re-evaluation at regular intervals, particularly if his complaints are not promptly and completely relieved by symptomatic treatment. It is in this way only that the frequently insidious onset of cancer can be detected without undue delay.

2. *Endoscopic Examination.*—Next in importance to the information obtained from the history and physical examination is the ability to directly visualize an internally located lesion. A simple speculum examination of the cervix uteri or indirect laryngoscopic visualization of the larynx are such useful and common procedures that they should form part of every general physical examination. Sigmoidoscopic examination of the lower ten inches of the large bowel can be performed with relative ease and should be performed much more frequently. Such an examination, if done routinely, will reveal an astoundingly large number of cancerous and precancerous lesions of the rectum and rectosigmoid even in cases with no local symptoms referable to the lower bowel. A specialist in proctology will seldom be easily available in small communities, and for this reason every general practitioner with reasonable dexterity should learn to perform sigmoidoscopic examinations or he should have available and utilize the skill of some other physician in his community. Cystoscopy requires even more skill, but it is not beyond the scope of general surgeons in small communities. If he is wise, the average general surgeon will limit himself to cystoscopic diagnosis, leaving the more difficult problems of treatment entirely to a skilled urologist. However, since urologists are not universally available, each community should have and should utilize the skill of at least one physician for cystoscopic diagnosis. Bronchoscopy, gastroscopy, thoracoscopy and other endoscopic procedures are more highly specialized examinations which may be beyond the scope of physicians in smaller communities. The need for such procedures is less frequent than for the more commonly used endoscopic examinations, but each physician should recognize the occasions when such specialized examinations are required and should promptly refer the patient to a competent specialist.

3. *X-ray Examination.*—Adequate roentgenological facilities are a sine qua non in the diagnosis of cancer. Adequate facilities include not only suitable x-ray and fluoroscopic equipment but the services of an experienced roentgenologist as well. The physicians of Austin and other communities throughout Minnesota have for several years employed the part-time services of expert roentgenologists from nearby urban cen-

ters. Such an arrangement cannot fail to improve the general standards of medical practice in a community and aid immeasurably in the early detection of cancer. The position of the general practitioner in the community is greatly strengthened thereby, and the improved quality and increased quantity of his practice more than compensate him for the work referred to the roentgenologist.

4. *Pathological Examination.*—The saying "Every tissue worth removing from the human body is worth examining microscopically," is not without merit. Not infrequently the pathologist discovers early cancer in the routine examination of tissue removed surgically in cases where the presence of cancer was not suspected clinically. Certainly most small hospitals cannot support a pathologist, but arrangements should be made with a competent nearby pathologist for the routine examination of all surgical and biopsy specimens. It is only logical that a higher percentage of practicing physicians will utilize the advantages of a biopsy in borderline cases when the arrangements have been made for the routine examination of tissue.

The nonavailability of a pathologist for frozen sections and the necessary delay when one must wait a few days for a pathological report are inconveniences that one must tolerate in smaller hospitals. However, in spite of the increased burden for the surgeon who does not have a pathologist on hand to share his responsibilities, the lack of immediately available pathological reports is not a very serious problem and need not jeopardize the patient. We would personally prefer the slightly delayed but reliable reports of a competent pathologist to immediate reports from a poorly trained resident pathologist. However, we must add that we do miss the personal presence of a pathologist, particularly the stimulus that the usually inquisitive and critical mind of one of that specialty adds to the practice of medicine. The status of the pathologist as a consulting specialized clinician must be maintained; and when more well-trained pathologists become available, every sizable community should seek to obtain a full-time pathologist.

5. *Surgery.*—The physician must be extremely critical in his evaluation of his own ability or the ability of others in his local community to handle the surgical treatment of cancer. Certainly minor cancers, such as many of the cutaneous cancers, can be treated by anyone reasonably skilled. However, cancers of the breast, gastrointestinal tract, and other organs require a maximum of surgical skill, as any operative procedure for such cancers must of necessity be of a radical nature if good results are to be expected.

The improved quality and quantity of surgical training in the past decade has gradually improved the standards of surgery in small hospitals, so that skilled surgical treatment of the more common types of cancer amenable to surgery is now available in many of our smaller communities. It is the author's opinion that this is a healthy trend, for regardless of the efficiency and impeccable reputation of our larger medical centers, many patients will inevitably remain at home for treatment unless the very nature of the disease absolutely demands highly specialized treatment, such as neurosurgery, which is available only in the larger medical centers.

6. *Irradiation Therapy.*—The ability to properly administer irradiation therapy in the treatment of cancer, like the surgical treatment of cancer is a specialized field and, here, too, no compromise should be made. Roentgen and radium therapy should be directed by a qualified radiologist at all times. It is our opinion that in certain fields, particularly the field of gynecologic malignancy, the treatment should be through the combined efforts of an experienced radiologist and a man experienced in the field of gynecologic malignancy. If such facilities are not available in a community, patients requiring this highly specialized type of treatment should be referred elsewhere. Here again, commensurate with increasing demands and with the increasing availability of well trained men, many of our smaller cities, such as Austin, soon will have available adequately trained men and adequate equipment for the treatment of these specialized cases of cancer.

In order to obtain an approximate idea of the volume and type of cancer work that a general surgeon in a small community encounters, we have analyzed the seventy-two new cases of cancer, referred to in Table I, that we have seen during a period of slightly over two years since returning to Austin after military service. It

should be emphasized that these cases do not, of course, represent an attempt to survey all of the new cases of cancer developing in this community nor do they represent all of the new cases of cancer seen by members of the Austin Clinic, of which the author is a partner. However, since a great majority of these patients were referred by fourteen general practitioners in Austin or nearby communities, the group is a fairly representative group of cases. In Table II, we have attempted to classify the reasons for delay in the diagnosis of the fourteen of the seventy-two cases in which the physician was held responsible for delay in diagnosis, according to the standards set by Leach and Robbins.[1] In all fairness to physicians of the Austin community, it should be noted that in seven of the fourteen cases where the physician was held liable for the delay in diagnosis, the error was attributable to physicians outside of Austin and the surrounding communities, often to physicians in larger medical centers, and in no case was improper treatment advised. In the majority of cases where delay in diagnosis occurred, the delay resulted in spite of apparent conscientious efforts on the part of the responsible physician; and in many instances, the very insidious nature of the disease itself was a sizable factor in the delay. However, it is obvious from Table II that the omission of such simple examination procedures as sigmoidoscopic examination, uterine curettement, biopsy and x-ray examination constitutes a major and inexcusable source of delay in the diagnosis of cancer. It is also apparent from Table II that physicians are too prone to rely on a negative x-ray report as infallible, often in the face of strongly suggestive symptoms. Under such circumstances, the author is reminded of an aphorism which Dr. E. L. Eliason of Philadelphia has often repeated for his students: "When the clinical and laboratory findings do not agree, repeat them both."

The various types of cancer encountered in this series are shown in Table III. It should be noted

that of the seventy-two primary cancers, there were five instances of multiple cancer. Three patients had new primary breast cancers at intervals of seven months, two years, and seven years after the first breast cancer. One patient had two separate carcinomas of the large bowel occurring almost simultaneously, and another patient had a resectable carcinoma of the transverse colon two years after the successful resection of a carcinoma of the cecum.

TABLE IV. TYPES OF TREATMENT

	Treated Locally	Treated Elsewhere
Major radical surgery	35	8
Major palliative surgery	4	1
Minor surgery, other than diagnostic procedures	10	3
Irradiation	0	4
Palliative non-surgical treatment	5	0
No treatment (refused)	2	0

A brief analysis of the type of treatment rendered the cases in this series is shown in Table IV. There were three operative deaths in our thirty-five cases where major surgery was performed in the hope of ultimate cure. These three cases were all gastric resections in poor risk patients, two of whom had acute, frank perforations of carcinomatous ulcers. Death was due to auricular fibrillation and cardiac failure in one case, surgical shock and aspiration atelectasis in another, and pulmonary embolism on the 14th postoperative day in the third case. There were two known deaths in the major cases treated elsewhere, one following a combined abdominoperineal resection, the other following a gastric resection. The immediate cause of death in these two cases is unknown. One hospital death followed major palliative surgery (cecostomy for the relief of acute obstruction), but the death was

AMNIOTIC FLUID AND MECONIUM EMBOLISM

S. STEVEN BARRON, M.D., RODNEY F. STURLEY, M.D., and DOUGLAS T. LINDSAY, M.D.
Minneapolis, Minnesota

IT IS the purpose of this paper to present two cases of maternal death from pulmonary embolism by amniotic fluid and meconium, together with autopsy findings, a brief review of the literature, and a discussion of the significant features of this rare condition.

It was first described in 1941 by Steiner and Lushbaugh, and in two papers they reported a total of ten cases. Since then Hemmings has reported one case and Gross and Benz have published a report of three cases. Steiner and Lushbaugh, in their original paper in 1941, thoroughly reviewed the literature to that date, and stated that they found no evidence of this condition having been diagnosed previously as a disease entity. However, they did find many reports of sudden, unexplained death occurring during or after labor with features similar to those they assign to this condition. In these instances, the older writers had ascribed various causes for death. These, to name a few, included hypersensitive vagus, obstetrical shock, idiopathic postpartum uterine atony with hemorrhage, acute pulmonary edema of pregnancy, "facultative invalidism" of the heart, eclampsia without convulsions, internal or external uterine hemorrhage, et cetera. De Lee (quoted by Steiner and Lushbaugh) had shown the symptoms to be similiar to those of anaphylactic shock. It is noteworthy that none of these cases reported previous to 1941 included a careful examination of the lungs.

Steiner and Lushbaugh discuss extensively the clinical and experimental studies they have made of this condition. Hence, we will not recapitulate all these details, but instead, we propose to present briefly only the most pertinent data. They offer the theory that during a strong or tetanic uterine contraction, amniotic fluid rich in either vernix caseosa or meconium or both is trapped in the uterus and is forced into the venous sinusoids, becomes embolic and lodges in the lungs. This would be favored if egress of amniotic fluid is blocked or if the fetal membranes are not ruptured at the cervix. Such an explanation would not be applicable to our first case, in which a cesarean section was performed before labor had begun. However, they also postulate the role of a possible tear in the fetal membranes or placenta as suggested in some cases with bloody fluid. After these emboli lodge in the smaller pulmonary arteries, a picture of anaphylactoid shock ensues. This probably is associated with reflex vascular spasm in the lungs and cardiac depression as in the case of pulmonary embolism of other types. As predisposing factors, they include uterine tetany or very strong contractions, meconium in the amniotic fluid, intra-uterine death of the fetus, oversized baby, multiparity and older mothers.

Clinically, the picture of shock is described as occurring during or soon after labor, often associated with hard and violent pains of uterine tetany. Listlessness, dyspnea, cyanosis and coldness accompany the drop in blood pressure to shock levels with a rapid, weak pulse that may become unobtainable. Occasionally there is vomiting and delirium. The duration of labor is not abnormal. Death occurred during delivery in two of their cases, up to eight and one-half hours postpartum in seven cases, and on the seventh day in another.

The pathological examination reveals the cause of death in all of these instances to be widespread embolism of the small pulmonary arteries (less than 1.0 mm. in size), arterioles, and capillaries. The emboli in the lungs consist of particulate matter found in amniotic fluid and meconium; that is, epithelial squamae, amorphous debris (vernix caseosa), lanugo hairs, and mucin thought to be from meconium. The blood vessels are dilated. Experimental data with rabbits and dogs, as reported by Steiner and Lushbaugh in the same paper, reduplicated the clinical and pathological findings of the human cases. For these experiments, they injected amniotic fluid and meconium intravenously.

The differential diagnosis is extensive and includes postpartum hemorrhage, placenta previa, abruptio placentae, pulmonary air embolism, vascular thrombotic pulmonary embolism, and eclampsia without convulsions.

No specific preventive therapy is available, since it is difficult to prevent excessive vernix caseosa and meconium or uterine tetany. For

From the Departments of Pathology and Obstetrics and Gynecology, Medical School, University of Minnesota, Minneapolis.

treatment of the established lesion, they recommend measures designed to combat shock, papaverine to abolish the reflex spasm of the pulmonary vessels, atropine to counteract the cardiac depression reflexes from the lung, and oxygen. Caution is urged against administering excessive fluids which might result in the formation of pulmonary edema.

Case 1.—Mrs. R. N. (U.H. 764084), a white woman, thirty-two years of age, was admitted to the University Hospital on April 11, 1946. The patient had had three previously uncomplicated pregnancies. The patient's last normal menstrual period was June 6, 1945. Her expected date of confinement was March 13, 1946. The patient developed a brownish vaginal discharge three days prior to admission to the hospital. Sixteen hours prior to admission she experienced a sudden loss of blood from the vagina unassociated with pain. Her local physician made a diagnosis of placenta previa and inserted a vaginal pack to control the bleeding while she was traveling to the hospital. At the time of admission, physical examination revealed the abdomen to be distended by a gravid uterus of term size. The fetus was in the L. O. T. position with the head somewhat displaced to the left of the inlet. The fetal heart was easily heard in the left lower quadrant. Since the patient was potentially infected as a result of the intravaginal packing, and because the patient was not bleeding at the time of admission, it was felt that delay in further management of the patient was indicated. The hemoglobin at the time of admission was 11.6 grams. The vaginal pack was removed and blood was made available for immediate transfusion. X-rays of the abdomen using soft tissue technique demonstrated the placenta on the anterior wall of the uterus well down into the lower uterine segment. Sixty hours after admission a moderate amount of fresh bleeding occurred. Vaginal examination at this time revealed an uneffaced cervix dilated two centimeters and through which placental tissue could be felt in all directions. The patient did not bleed following examination. Her pulse and blood pressure were normal. A classical cesarean section was done under local anesthesia allowing delivery by breech extraction of a male infant weighing 4190 grams. The placenta was situated on the anterior inferior wall of the uterus and covered the cervical os. It was removed manually following delivery of the child. The uterus contracted firmly and very little bleeding occurred. The amniotic fluid was very heavily stained with meconium and had a greenish, bile-colored appearance. It contained many small particles of bile-stained vernix. The infant made two respiratory efforts but did not inspire. The respiratory tract was filled with the green amniotic fluid which could not be aspirated with the bulb syringe. Bronchoscopy was done at once but the material could not be aspirated even with mechanical suction. The infant died in five minutes. Following delivery of the infant, the patient complained of rather severe pain in the abdomen and she was given 375 mg. of pentothal intravenously. Approximately five minutes after induction of the pentothal it was noted that the blood in the operative site was getting dark. A few seconds later it was noted that the patient was not breathing. An airway was inserted immediately and artificial respiration started. The patient's pulse and blood pressure were not perceptible. Palpation of the aorta and auscultation of the heart revealed death of the patient. There were no warning signs such as gradual drop in pressure or alteration of the pulse. The patient expired about seven minutes after the uterine wall was incised and five minutes after starting the pentothal anesthesia. Autopsy consent was obtained for infant and mother.

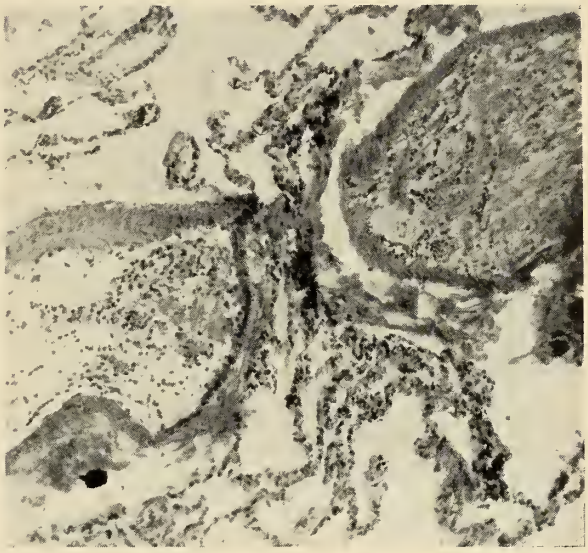

Fig. 1. Case 1. Photomicrograph demonstrates two small pulmonary arteries filled with protein material and leukocytes.

Autopsy report (A-46-593) *Mother.*—Pertinent findings grossly were few. Cyanosis was present and there was an 18 cm. midline, lower abdominal surgical incision closed with silk. The heart weighed 280 gms.; no gross abnormalities were found. There was no pulmonary thrombotic or air embolism. The lungs weighed 230 and 200 gms. on the right and left, respectively; grossly nothing abnormal could be found, no meconium, thrombi, emboli, infarcts or edema. The uterus extended 16 cm. above the symphysis and showed a closed anterior incision for cesarean section; the site of attachment of the placenta was seen around the internal os. The uterine wall was up to 4 cm. thick. Otherwise, the genital organs were normal, as were the remaining organs and systems of the body with the exception of a persistent urachus. Examination of the brain was not permitted.

Microscopic Findings.—

Lung: The small arteries, arterioles and capillaries were filled with epithelial cells, protein material in strands, and leukocytes, with remarkably few erythrocytes seen. The parenchyma was otherwise normal.

Uterus: Some of the sinusoids were filled with cells

suggestive of epithelial nature. The other changes were typical for the regnant state.

Breast: There were changes typical of the gestational breast with large lobules of acini in which fat globules were seen.

Urachus: This contained a dense polymorphonuclear suppurative exudate in its lumen. Heart, spleen, kidney, liver, ovary and lymph nodes were all normal.

Autopsy Report (A-46-592) *Fetus.*—Gross appearance: The child was a well-developed male infant weighing 4150 grams. The eyes were normal, the sclerae not icteric. The skin was not macerated, but all cutaneous folds and recesses were filled with vernix caseosa which was stained a marked yellow from pigment in the amniotic fluid. The color of the umbilical cord was a dark yellow-green. The abdominal viscera were essentially normal to gross inspection. The stomach and entire small bowel were distended with a thin greenish-yellow fluid. No meconium was found in any portion of the gastrointestinal tract. The right lung weighed 105 grams, the left 70 grams, neither floating in water. The pleural surfaces showed multiple white blebs (ruptured alveolae) on a reddish-purple background. No crepitant areas were palpable. The cut surface of the pulmonary tissue released a profuse yellow-green fluid, somewhat tenacious in the bronchi and trachea. Other organs were grossly normal. The cranial vault was not examined.

Microscopic Findings.—The lungs showed no areas of normal alveolar structure. The majority of bronchioles were incompletely blocked by desquamated epithelial cells with occasional ones showing a yellowish granular material, and, rarely, fibrous strands suggesting lanugo hairs. Generally the alveolae were distended, the content being a fine granular precipitate, with occasional epithelial cells. The pulmonary vascular bed contained only normal cellular elements. The pancreas showed acini and ducts dilated by inspissated debris, mild cystic changes in the tubules. The other organs were not worthy of special comment as to microscopic appearance.

Case 2.—Mrs. V. N., a primiparous, white woman, thirty-one years of age, was admitted to a local hospital in labor at 10:00 P.M. on March 20, 1941. The pregnancy had been uneventful until three hours after onset of labor. At that time a small amount of uterine bleeding occurred which persisted until delivery. Five hours after admission she was delivered of a normal living infant by low forceps. The labor pains were not recorded as being unusual. Two minims of pituitrin were given by hypodermic injection 30 minutes prior to delivery. Moderate bleeding occurred following the delivery which was not checked by the expression of the placenta. The patient was given ergot and pituitrin subcutaneously with no appreciable effect upon the contractility of the uterus. The cavity was then packed with gauze. Intravenous gum acacia was administered and the patient prepared for laparotomy. A blood transfusion was started and the abdomen was opened. Clamps were placed on the uterine vessels, but the patient expired suddenly at this point.

Autopsy Report (A-41-672).—There was no cyanosis. A 10 cm. midline abdominal incision extended above the symphysis and had eight sutures in place. The peritoneal cavity contained about one liter of serous fluid, and the heart, lungs, liver and spleen were normal grossly. The uterus was globular in shape and measured 24 cm. in length and 12 cm. in width; the cervix was 8 cm. long. A laceration measuring 8 cm. in length and 12 mm. in depth began at the internal os and extended through the thickness of the lateral wall of the uterus. In the broad ligament opposite this laceration was a large hemotoma. A smaller laceration was found on the opposite side of the uterus, arising at the internal os and extending upward 3 cm. but not through the entire thickness of the wall. The cervix showed no gross tears.

Microscopic sections of the lungs showed a mucinous material filling the small arteries; numerous epithelial squamous cells were seen, and there was a marked reduction in the number of blood cells in these vessels. There were no thrombi in any vessels. The remainder of the lung parenchyma was normal. Section of uterus showed considerable necrosis of the myometrium beneath the tear. The remainder of the examination was without note.

Discussion

The first description of amniotic fluid embolism to the maternal pulmonary system by Lushbaugh and Steiner in 1941 offers an explanation for some otherwise unexplained sudden maternal deaths. The second report published by the same authors in 1942 included a case almost identical with Case 1 in our report. Their patient died following cesarean section for placenta previa. In the two patients delivered by cesarean section we must assume, as they do, that the fluid gains entrance to the maternal circulation through the open veins of the uterine wall at the site of the incision. It is sufficient to say that the obstetrician should consider this newly described lesion when confronted with profound shock during and after labor or the sudden unexplained death of the patient.

The diagnosis is conclusively made in cases such as these only pathologically. Grossly, there is a paucity of findings, but other causes of sudden death should be carefully searched for. These include pulmonary embolism both by thrombus and by air and other cerebral and cardiac pathology. Only by microscopic examination are the classical features found. These consist of meconium, mucin, lanugo hairs, vernix caseosa, and

(Continued on Page 97)

History of Medicine In Minnesota

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

(Continued from December issue.)

Dr. Justin M. Hull came from Cook County Hospital and located at Albert Lea in April, 1874. He re-located the same year at Lake Mills, Winnebago County, Iowa. He is claimed a pioneer physician of that county and his history is recorded there. Records reveal however, that he did practice for short periods at Alden and Albert Lea. He was the son of Rev. O. P. Hull and was born in Dane County, Wisconsin, July 9, 1845. He served fourteen months in the Third Wisconsin Volunteer Cavalry, from 1862. He graduated from Bennett Medical College, Chicago, in 1873.

"Dr. Hull was one of the pioneer physicians of Winnebago County, having located in Lake Mills in 1874 and continued in practice until his death in April, 1889. He was a man of powerful physique, endowed with an unusual amount of personal magnetism, an apt student of human nature, and accurate in his estimates of men. He was eminently fitted to attract and hold a large circle of friends."—*Winnebago County History*, 1917.

Dr. H. H. Wilcox was born in South Carolina, December 28, 1850, and was a child when his parents moved to Kentucky. There he grew up; and after finishing school and teaching for a time, he entered the Cincinnati Medical College, where he graduated with honors, receiving a gold medal for his excellent scholarship. He married Ellen Abbot of Kentucky, in 1875. In 1877, with his wife and infant son, Leslie, he moved to Glenville, Minnesota, where he practiced his profession for several years and where his twin daughters, Gussie and Jessie, were born. He moved to Albert Lea in 1883, where he continued an active practice for many years. He established a private hospital later and for a time edited the *Albert Lea Medical Journal.* He took an active part in local and state politics, served as mayor for one term and as city health officer at different times. In 1905 his wife died, and a few years later he married Laura Hydorn. To this union one son, Richard, was born. He was a member of the Methodist Church, Western Star Lodge, and Apollo Commandery (*Albert Lea Evening Tribune*, December 15, 1925).

Dr. Wilcox was a solid general practitioner. He was apparently well read in medicine and surgery, and was filled with the urge of spreading the knowledge of modern medicine relating to isolation, antisepsis, disinfection, and sanitation in infectious and contagious diseases as revealed in the 1880's by Pasteur, Koch, Lord Lister, Loeffler, Elrlich, and others.

"Dr. Wilcox proposes to issue the first number of *the Albert Lea Medical Journal*, a monthly publication devoted to modern medicine, surgery, and prophylactic medicine. The *Journal* will be 7 in. by 10 in. in size and contain twenty pages of reading matter. The first issue will consist of one thousand copies. The long experience and practical ability of Dr. Wilcox, and his high standing as a citizen, is sufficient voucher for the character of the publication and should recommend it to the profession and the public and assure its success."—

Standard, August, 1898. "The *Journal* scintillates with wise and keen observations, which the general reader, equally with the profession, cannot fail to enjoy."—*Standard,* November, 1898.

The *Albert Lea Medical Journal* was published only a short time. There are a few copies—the only ones known to exist—in the library of the Minnesota State Medical Association in St. Paul.

Dr. Wilcox had a good command of the English language and contributed freely, to the local press, articles relating for the most part to problems of health and sanitation. In 1896 he contributed a splendid article on "Contentment," in which he deplored the fallacy of sending patients away to Colorado or to other dry climates for the purpose of regaining health. "There is something nice," he wrote, "about dying at home anyway; but how dreadful the thought of some poor homesick youth dying by inches away from home and among strangers. Think carefully before you send anyone away from home; then don't send them but go and take them." In November, 1896, he contributed an article titled "Tuberculosis" (Consumption) in which he describes it as a contagious disease, explains methods of transmission, urges strict isolation, and advises care in disposing of sputum and excretions. In the same month he contributed a long well-written article on diphtheria and quarantine, giving details of early history and quotations from ancient writers, showing that they were familiar with this malady. He describes also the work of Loeffler in isolating the bacillus, outlines modes of infection, and urges early call of a physician to establish diagnosis.

Dr. Wilcox was an ardent temperance man, and in December, 1896, contributed an article on liquor and the physician under the title "Medical Talks."

"Alcohol is a medicine of no little consequence. It is a stimulant, tonic, narcotic, sedative, nutrient, irritant, antiseptic, and antiphlogestic. It will make the rich man poor and the poor man rich. It will increase appetite and set up catarrh of the stomach. It will increase activity of the liver cells, causing the liver to enlarge, then reduce it to a nutmeg lump. It will increase a feeble heart to quick action and reduce a strong heart to weak action. I do not hesitate to prescribe it for those whom I know, and think need it."

At a meeting of the Science Society, February, 1892, Dr. Wilcox presented a paper on psychosomatic phenomena. "It was historical and many illustrations were given of unexplainable dreams and hallucinations. The discussion was lively."

Dr. Wilcox was nominated for the office of county coroner on the Farmers' Alliance ticket in 1890. In declining this nomination, he told that in his boyhood in Kentucky his father and brother served in the Union Army; that he had cast his first vote for General Grant, and later had voted for Hayes, Garfield, and Blaine, whose party had fought to save the Union and that now this party was "neglecting to take radical measures by which we might be emancipated from the whiskey curse. My anxieties to suppress the whiskey evil arose to John Brown proportions, and because I could not proclaim them freely in the Republican party, I joined the Prohibition party." Dr. Wilcox was elected to the office of mayor of Albert Lea in 1890. In 1891 he was appointed surgeon of the Minneapolis and St. Louis Railroad. In 1894 he was a candidate for state senator, highly endorsed by the press as honest, honorable, and able. In 1906 Governor Cole I. Crawford of the State of South Dakota appointed Dr. Wilcox surgeon in charge of the state soldiers' home at Hot Springs, a position that he retained until his death there in December, 1925.

Dr. S. H. Washburn located at Albert Lea in June, 1876, with offices over Wood's drug store. He came from Hattisburg, Illinois, and practiced here about two years and then located at Mason City, Iowa, where he had a large practice.

Dr. F. W. Beck located at Albert Lea in August, 1878. He practiced here less than two years and acquired a large circle of friends during his residence here. Unfortunately, Dr. Beck was a confirmed alcoholic and soon got into trouble. "He was a young man of fine talents and of rare attainments and was highly esteemed by those who knew him."—*Standard,* Aug., 1878. Dr. Beck died at his home in Chicago in August, 1879.

Dr. Johanna Disbro, "a graduate of the medical department of Iowa State University, left a practice in Centerville, Iowa, to bring her brother, a consumptive, to Minnesota. She practiced at Albert Lea in 1883. The following year she married a Mr. Crawford of Minneapolis. She was a homeopath.—*Excerpts, Nora Guthrie.*

"**Dr. W. T. Leonard** of Mauston, Wisconsin, locates at Alden. He appears to be a perfect gentleman and one who knows his business. He comes highly recommended for his ability and integrity. He is a blue-ribbon temperance man." *Enterprise,* May, 1878.

Dr. Leonard was not at Alden very long, perhaps less than a year. A local newspaper item in 1879 states that he returned to Alden for a visit—but where he went is not known. In 1900, according to the medical directory of that year, he was located at Campbell, Wilkin County.

Dr. R. C. Pinkham announced his location at Albert Lea in 1879 by a newspaper item stating he was "permanently located at Albert Lea. I devote my entire time to treatment of chronic diseases. I will cure a case of hemorrhoids in ten days; female weaknesses a great specialty."—*Enterprise,* July 24, 1879. He evidently was an imposter as no further record is found to indicate that he established a practice at all.

"**Doctor ——— Green,** from the west part of the county, attended an accidental shooting and removed a bullet."—*Standard,* 1876. Dr. Green evidently moved to Windom, Minnesota, as a local notice in the *Standard* of June, 1879, states that he returned from that place to Alden on a visit.

Dr. Eugene M. McCord was born at Titusville, Pennsylvania, in 1854, but spent most of his early youth at Waverly, Iowa. He came to Freeborn County in 1877 and entered into partnership with Dr. W. H. Smith, coroner, in the drug business and in practice. In the files of the local newspapers for May, 1878, there is an item to the effect that Dr. Smith and Dr. McCord conducted a post-mortem examination and stomach analysis in a case of death by strychnine poisoning. Another item in an issue in October, 1877, states:

> "I have purchased the drug store formerly owned by Dr. G. W. Bark and propose to continue in the same old stand. I am a druggist and when I say druggist, I mean a compounder of medicines, understanding the business from A— to izzard. Physicians' prescriptions carefully compounded."

He apparently had studied pharmacy and read some medicine in Philadelphia before locating at Albert Lea in 1877. An item dated Sept., 1878, states that "Dr. McCord left for Philadelphia to take a course of lectures in one of the leading medical colleges in the country." Another item, dated March, 1879, says:

"Dr. McCord will hereafter keep a temperance drug store. You can always find pure drugs, medicines, and chemicals for prescriptions. We only ask you to try our 'Bitter wine and iron,' which is a pure extract of roots and citrate of iron preserved in the best quality of grape wine, and no poisonous compounds calculated to kill more than it cures." An item dated April, 1879, says, "Diphtheria is a disease caused by blood poisoning and the best way to save your children from the dreadful scourge is by taking 'Bitter wine and iron,' found only at C. W. McCords." An item dated August, 1881, states that Dr. McCord was representing a wholesale drug firm of Chicago. Another item, October, 1882, states that he was publishing a paper in Jasper County, Nebraska.

He did, however, finally graduate in medicine, namely, from the Jefferson Medical College, Philadelphia. He then moved to Luverne, Minnesota, and in 1884 located in Saint Paul and enjoyed a long and extensive practice there, serving for a number of years on the Saint Paul City Hospital staff. He died in Saint Paul in December, 1913. His obituary appeared in the *Pioneer Press,* December 22, 1913.

"**Dr. Oscar H. Trenkler**, formerly of Portage, Wisconsin, a medical graduate from Germany and a practicing homeopathic physician in the United States for twenty-two years, locates at Albert Lea."—*Enterprise*, Aug., 1879. Dr. Trenkler moved to Mankato in May, 1881.

Dr. ——— Preston, born in Connecticut, located at Alden in 1878. He is described as a pleasant and agreeable gentleman and given much credit for his skill as a surgeon and as a general practitioner. He sold his drug store and practice to Dr. H. V. Perry in 1880 and moved to Youngstown, Ohio. He later returned to the West and located at Decorah, Iowa, where records state that he earned a high reputation as a physician. In April, 1889, he returned to Freeborn County, bought the drug store at Alden, and was again welcomed with a good practice. In a very short time he again sold out and returned permanently to Youngstown, Ohio.

Dr. Arne Nelson located at Hartland in 1878. He practiced there through 1879, and in 1880 located at Aldal, Polk County, Minnesota. People now living at Hartland remember him as practicing there only a short time.

Dr. John R. Jones was born in Green County, Wisconsin, in 1853. His father and mother both came from England. His mother died when John Richard was a small boy. His father married again and came to Freeborn County in 1867. John attended high school at Albert Lea, attended medical schools in Cincinnati and Chicago, then read medicine with Dr. Rowland of Twin Lakes, and no doubt practiced some with him. Dr. Jones did no private practice in this county but did practice for a time at Fertile, Iowa. He married Zella Williams, a half sister of Dr. Rowland's wife.

Dr. H. V. Perry came to Alden in 1880. "We understand that Dr. Preston is about to transfer his extensive practice to Dr. H. V. Perry, M.D., of White Hall, New York. Dr. Perry is a man of culture and fine abilities and well worthy of the confidence and patronage of our readers, having had in addition to a thorough course at Washington Medical University of Baltimore, Maryland, the honor and advantages of being nearly two years the resident physician in the hospital connected therewith and also several years' experience in private practice."—*Alden Eagle,* January, 1880.

Much of Dr. Perry's time at Alden was devoted to the drug business, and in 1887 he moved to Albert Lea, where he bought a drug store. There is no record of his doing any general practice here. He was not married.

In 1888 Dr. Perry sold his stock, drugs, and other goods and moved to Ellensburg, Washington. "Dr. Perry reports that he is doing well and having a profitable drug business besides his practice."—*Standard,* March, 1888.

Dr. E. M. Woodring was evidently a pioneer doctor of unusual ability and high intelligence. He came to Albert Lea late in the year 1880 and established a partnership with Dr. W. W. Smith, which continued through 1881. He was born on a farm in Green County, Wisconsin, date unknown, and was for a time telegraph operator at Mendota, Minnesota. He entered the Ohio College of Medicine and graduated with highest honors, taking the faculty prize in 1880. He practiced for a time at Green, Iowa, before he came to Albert Lea. He was regarded by all as a gentleman but in some respects as strange in his conduct. His associates at the college hospital in Ohio, where he was an assistant professor lecturing in medicine, stated that he often showed signs of marked excitability.

When he moved to Minneapolis in 1882, he became involved in an assault that resulted in arrest and conviction. Dr. Woodring had ordered an operating table from the Knickerbocker Company. The next day he returned the table, remarking that if he could secure a suitable table he would accept it and pay for it. The table was placed on the sidewalk and the following notice placed on it, "This table is brought back from Dr. Woodring's office because he would not pay for it and is for sale cheap." Soon afterwards, on meeting Mr. Knickerbocker on the street, an altercation arose, ending in the doctor's saying, "I will fix you in two hours." He consulted as to his legal rights in the matter and returned to his office. Here he armed himself with a long sharp knife of razor steel, used in hip and thigh amputations. Concealing this in his sleeve, he returned to Knickerbocker's store, where he found the offensive note again displayed on the table. During the ensuing altercation he drew his knife and made a lunge at Mr. Knickerbocker, but the latter deflected the blow and caught the blade above the elbow, which penetrated the axilla, missing the artery. Two employes overpowered the doctor, but in the struggle one was severely cut on the head. The doctor was promptly arrested, but released on bond of $1600 secured by Dr. France, Dr. Abbott, and Dr. Small. His trial drew a sentence of penal servitude, but his bondsmen and other influential friends secured a governor's pardon. The foregoing consists of quotations taken almost verbatim from *Albert Lea Enterprise,* May, 1882. Judging from the action of prominent bondsmen and other friends, Dr. Woodring must have been held in high regard by his colleagues and the public in general.

Dr. L. C. Biglow, a brother of C. S. Biglow of Owatonna, located at Albert Lea in March, 1880. He came from Muscatine, Iowa. He attended the State Medical Association's meeting in June, 1881, but in July of that year moved to Denver, Colorado.

Dr. M. L. Cutler, physician, surgeon, and electrotherapeutist, located at Albert Lea in 1880. He was born and raised at Osage, Iowa, came to Freeborn County from Frankfort, Iowa, and had a long experience in his profession. He practiced here only a short time and moved to Dakota City, Iowa, in 1882. An item appearing in the *Freeborn County Standard,* August, 1890, reads as follows: "Dr. L. M. Cutler, a former resident of Albert Lea, now of Saint Paul, was found dead in bed. His family was away at the time. Death was supposed to be due to heart disease. Autopsy revealed hemorrhagic ulcers of the lungs."

Dr. Melchoir Magelssen was born in Christiania (Oslo), Norway, in April, 1852. His father served as chief of police in the city of his birth until 1859, when he moved to Bergen, Norway, where he was made a magistrate. Dr. Magelssen came to America in 1881 and located at Albert Lea, in 1882, where he had a good practice until 1888, when he moved to Fergus Falls. He married Elizabeth Marie Hansen in 1883. To them one son was born in 1885. He died at Fergus Falls in 1895, aged 43.

The subject of this sketch spent his early days at school, attended the Latin College of Bergen (roughly equivalent to an American college) until 1869, when he entered the University of Oslo, from which he received a diploma as physician and surgeon in 1876. He continued his medical studies at the Royal University of Vienna, Austria, graduating in 1879, and completed his education in France. He then located in London, England, where he had a good practice, still continuing to study. He spoke and read the three Scandinavian languages besides English and German. He had a colorful personality, but the caste system of the old world, receiving accreditation by his contacts in Vienna and London, gave him an exaggerated notion as to the treatment physicians should receive from the general public in America. From a personal interview with a gentleman who knew him quite well, the following dictation was taken:

"Among other things, he felt that he was entitled to the right of way on highways, and he generally selected the middle of the road. This got him into a great deal of trouble with folks he met on the roads and trails, especially when the snow was deep in the winter and in the springtime when roads were narrow or breaking up. I recall that one time he published an advertisement to the effect that, on and after a certain date, he would display in a prominent window, the names and addresses of patients who owed him money and paid nothing on accounts for thirty or sixty days. He did post this list, and it caused considerable talk around town. Some disputed the accounts and threatened suit against him; some gave him severe tongue lashings; and a few landed short hooks to the jaw. I recall that the doctor said that, between the time of his advertisement and the publication of his list, collections were brisk."

While in Albert Lea he was offered a position as surgeon in a Brooklyn hospital, but he refused the appointment because of his large practice here.

He was an able, well-qualified physician and surgeon and a gallant gentleman; but in comparison with his illustrious cousin, Dr. Jacob Magelssen of Rushford, his paths through life had not encountered the rough detours that provide the kind and amount of gravel in one's diet that seemed to be needed in the making of an American of his day.

Dr. ——— Torkelson was a druggist and established the first drug store in Hartland in 1882. All druggists in those days prescribed medicines over the counter, and so he was called "doctor." An item in the newspaper in 1886 states, "Dr. Torkelson, our doctor, druggist, and postmaster, is dead." He died of consumption.

Dr. Paul C. Jensen was born in Copenhagen, Denmark, April 7, 1855, and spent his boyhood and had his early schooling there. At the age of fourteen, in 1869, he accompanied the family to America, where they settled on a farm southwest of Blue Earth in Faribault County. He next came to Albert Lea and found employment in the Wedge and Spicer drug store. In 1877 he entered the University of Michigan College of Pharmacy. Following his graduation there he immediately entered the medical school of that university, from which he graduated in 1882. He began practice at Albert Lea, but after about a year and a half moved to Chicago, where he was soon appointed assistant city physician. In 1889,

he married Miss Kathryn Hansen of Glenville, Minnesota, who within a year died in childbirth. He moved the same year to Manistee, Michigan, specializing in ear, nose and throat diseases. Twice he held the office of city physician, his first term involving a severe epidemic of smallpox. His second term began in September, 1926, and continued until his death. His official duties caused him serious financial losses in his private practice. Dr. Jensen was identified with county, state, and national medical societies and contributed articles to the medical journals. From his obituary the following sentence is culled, "All who knew him agree that he was an example of practical Christianity, tender as a husband, loyal as a friend, hospitable and cordial in the home, and sympathetic in the sick-room." On September 12, 1900, he married Dorothy Dimple Peach. No children were born to this union. He died of heart disease at his home in Manistee in the summer of 1931.

Dr. G. A. Stevenson, physician, surgeon, and specialist in diseases of the rectum, eye, ear, nose, and throat, was born near Chatfield. He located at Alden in 1884. A card dated April, 1886, reads:

"Dr. G. A. Stevenson, rectal diseases a specialty, cure painless, no knife or ligature used in treatment, cure guaranteed; piles, fissure, fistula. Send for illustrated circulars. Brinkhoff system used."

In January, 1887, Dr. Stevenson moved to Albert Lea but retained a partnership in the practice and business he sold to Dr. Cannon at Alden. In March, 1888, he moved back to Alden to practice but the same year sold his home to Dr. Cannon and returned to Albert Lea after taking postgraduate work in diseases of the rectum. In 1890 he attended the Chicago Polyclinic, taking a "refresher course." In 1891 he felt that his specialty was detracting from his general practice, as would be indicated by the following notice, "Dr. Stevenson has added an attractive sign to his windows and they are so plain that he who reads may run, and he who hears may learn that he is successfully treating all diseases."—*Enterprise,* January, 1891. "Dr. Stevenson moved to Alden Township, where he owns thirteen hundred acres of Freeborn County dirt, but will be in Albert Lea part time to look after his special practice."—*Enterprise,* October, 1892. In December, 1894, "Dr. Stevenson returned to Albert Lea as a permanent citizen. He rented his stock farm in Alden Township and bought a beautiful lot on Park Ave., Albert Lea."—*Enterprise,* December, 1894. He never did build a home on this lot, and as he refused to sell at a good price, it was finally turned back for taxes. In the early 1920's he went to Europe and studied eye, ear, nose, and throat work in Vienna. Returning in about two months, he practiced his specialty in Albert Lea and surrounding towns for a number of years, but retired in the early thirties.

Dr. Stevenson was a bright man, but he wrote his own ethics and lacked in human understanding. As with many, the doors were not guarded against some of the human frailties. He was a good doctor and did much good in an irregular way. He died an old man.

(To be continued in the February issue.)

Ernest M. Hammes, M.D.
President, Minnesota State Medical Association

President's Letter

THE COMING YEAR

I wish to take this opportunity to express to the members of our Association my appreciation for bestowing upon me the highest honor in the Minnesota State Medical Association. Having served on many committees and on the council for several years, I fully realize that the responsibilities and duties of your president will be greatly lightened by the continued co-operation of and assistance from these various committees. It has always been a marvel to me how regularly committee members attend meetings in Saint Paul, in rain or shine, and frequently travel long distances in spite of snow and icy roads. To the Twin City members this is a light chore by comparison. But such is the co-operative spirit of the members of our Association, resulting in the high standard of accomplishments by our medical profession.

The most delightful part of my new job will be to have an opportunity to meet my many friends at county medical meetings, and I do hope I shall be able to attend many of them. The only regret I have is that my office as councillor of the Fifth District has terminated. Your president is expected to attend all Council meetings, but he does not even have a vote in Council matters. Serving on The Council has been a most delightful and instructive experience, and a privilege to be associated with men whose wholehearted effort is to adjust and solve the many problems that confront our State Medical Association. I can assure you that some of these problems have been serious, necessitating long hours of deliberation, frank discussions, keen judgment and conscientious efforts. Men like Dr. L. L. Sogge of Windom, who has served on The Council for twenty-three years; W. W. Will of Bertha, for twenty-one years, W. L. Burnap of Fergus Falls, for fourteen years, and others have given of their time, ability and energy to an unlimited degree. This service can never be repaid, and we can only express our appreciation for their long and untiring service.

I should like to correct some erroneous impressions. I have been told on several occasions that members of The Council attempt to be self-perpetuating. Your councillor is selected by the members of the county societies from his district. His name is presented to the House of Delegates by his district at the annual meeting, and he is elected by that body. Members of The Council do not even have a vote in this election. Another complaint that has been voiced is that members of our State Medical Association have been unable to appear before The Council to present their problems. I am sure that if such a request is made to Mr. R. R. Rosell, our executive secretary, he will arrange that any member of our Association will be invited to The Council meeting and will be given ample time to discuss any important matter. Members of your Council are your elected servants, and their only desire is to keep our ball rolling smoothly, ethically, medically, professionally, and politically.

I fully realize that during the coming year many problems of a serious nature will arise. With our state legislators in session and a Congress in Washington with a dubious attitude toward scientific medicine, measures may be instituted, detrimental to the medical profession, but more important, detrimental to the public as a whole and to the progress of scientific medicine. I feel confident that the untiring effort that every member of our State Medical Association has manifested in the past will undoubtedly continue during the coming year. With the able assistance of Manley Brist, our legal adviser, and R. R. Rosell, our executive secretary, our ship will sail through these turbulent waters, and scientific medicine will maintain its high degree of efficiency in every field.

In closing, I wish you and yours a healthy, happy and prosperous New Year.

President, Minnesota State Medical Association

Editorial

THE TWENTY-FIVE DOLLAR ASSESSMENT

SOME see in the re-election of President Truman a mandate to Congress to pass a compulsory national health insurance bill. If this proposal had been a plank in the Democratic Platform, such a view would have some weight. Simply because the President has gone on record as approving the Wagner-Murray-Dingell Bill and was re-elected does not mean that everything he has favored should be considered by Congress as a mandate. The Democratic platform states, "We favor the enactment of a national health program for expanding medical research, medical education and hospitals and clinics." Compulsory health insurance is not a part of the party platform.

Since the election, Oscar Ewing, Social Security Administrator, has been carrying on an active one-man campaign by radio, press conferences and announcements issued from his office insisting on the need for this legislation and making extravagant statements about what nationalized medical care would do for the health of the people. He has tried to break down the confidence of the public in the medical profession by every known technique and has made such statements as the lives of 140,000,000 persons are more important than the wishes of 180,000 physicians. This, of course, infers that the profession is opposed to this legislation for selfish reasons. If Ewing's statements that 300,000 lives could be saved if only his proposals were adopted and that 70,000,000, or half of the population, are without proper medical care were true, he would have a good argument. No one can deny that medical care in these United States is better under the present private enterprise than in any other country in the world under governmental control of medicine. Governmental control in this country would similarly result in deterioration in medical practice.

We have had, since November 2, a sample of the tactics which are to be used by the proponents of national health insurance. These individuals have the advantage of the use of millions (some estimate $70,000,000.00) of governmental funds for propaganda use. Although such use of tax funds is absolutely unconstitutional, this practice continues.

Compulsory sickness insurance, notwithstanding misleading propaganda to the contrary, is a variety of socialized medicine or state medicine and possesses the evils inherent in any politically controlled system. It results in deterioration of medical care. This is the main reason why we, as a profession, oppose it.

We repeat the statement that state medicine is a forward step in the eventual socialization of the entire national economy. We, as a profession, are not alone in our championship of private enterprise, and we should and will have powerful backing from others who value freedom of enterprise rather than socialism.

The issue is becoming more clear-cut as one between voluntary sickness insurance and compulsory government insurance. It is perhaps not generally known that over 32,000,000 individuals are now protected by Blue Cross hospital insurance; that the number of individuals covered by Blue Shield medical policies has jumped from 2,845,000 in 1946 to over 10,000,000 in 1948; that commercial indemnity companies cover an additional 20,000,000 for hospital care, 15,000,000 for surgical and 2,000,000 for medical care. Soon it will be as foolhardy not to insure against catastrophic sickness as against fire. Thus, voluntary insurance is doing much and will do more to help meet the admittedly high cost of sickness, and this is a good argument against the need for compulsory insurance.

If the public wants compulsory health insurance with at least a 4 per cent wage deduction, with increased bureaucracy and regulation in Washington, they will obtain it. We believe that a well-informed public will prefer to continue the present status of medical practice. The medical profession has accepted the task of informing the public. By unanimous vote of the House of Delegates assembled in St. Louis in December, our delegates

pledged our membership to self-assessment of $25.00 per member to provide the necessary funds to carry out the enormous task of informing the public about the issue. We have the handicap of unscrupulous opponents with many more millions at their disposal for propaganda purposes. Ours is not an impossible task. The story of Governor Warren's effort to put over state medicine in California is reassuring. The medical profession of the state assessed itself $100 a year for three years and by a superhuman effort was able to combat the opposition of a coalition governor and the labor unions and prevent the passage of the bill by a majority of one vote in the legislature.

Physicians pay no dues to the AMA. County society membership automatically makes them members of the AMA. Subscription to an AMA publication makes them fellows of the Association, and such subscriptions barely cover the cost of the publication. Even the increase in subscription dues (so-called Fellowship dues) from $8 to $12 in 1947 has not prevented the Association from going in the red.

We sometimes hear our fellow members inquiring why the AMA does not do something to stem the recent current towards government control of medicine. The AMA is now going to do something and requires the contribution of $25 from every member. A national planning committee has been appointed. The Washington office will be enlarged, and publicity experts will be employed. The bulk of the money raised will be used to inform the public on the issues involved. With the knowledge of the seriousness of the present situation which we have attempted to outline, there should be no dissenting voice.

PUBLIC RELATIONS

ON December 3, 1948, the Friday preceding the interim session of the American Medical Association held in St. Louis, representatives of forty-three states and Hawaii met to discuss public relations. The meeting was such a success that a similar but expanded meeting will be held at the next interim session.

Some interesting thoughts were expressed which merit emphasis.

No matter how efficient any group may be, it has to be sold to the public. This does not mean that every individual physician or medical group should blow its own horn, but it does mean that the accomplishments of medical science and the superiority today of medical attainments in our country over those in any other country should be publicized. We, as a profession, have been somewhat, but not wholly, lax in publicity activities. Such publications as *Hygeia*, radio broadcasting and newspaper articles on health subjects have partially supplied the desire on the part of the public for medical information. Yet the newspapers complain of the difficulties they encounter in obtaining medical news. Provision should be made for news releases in connection with all medical meetings by some designated individual or committee.

After all, the individual physician is the best medical publicity agent in the world. There is nothing new in this statement. Physicians have always used their personal contact with patients in building their practices. But relatively few realize their opportunities in daily contact with patients for disseminating the facts relating to the advantages of the American system of private practice over governmental control.

The physician as an individual can sell the present system of private practice in other ways to the public. He can see to it, when unable to make a call or when the nature of the case is outside his particular field, that the call is filled. He can consider the patient's pocketbook in the matter of unnecessary calls, needless hospitalization and laboratory procedures and overcharging. Avoidance of unnecessary operative procedures should not have to be mentioned. The application of the Golden Rule is all that is necessary. The doctor who breaks the Golden Rule in these respects more than counteracts the good public relations accomplished by the many.

We, as a profession, have laid ourselves open to considerable criticism, in that patients too often encounter difficulties in obtaining a physician's services at night or in case of an emergency. A constructive step in correcting this situation and in thus improving our public relations is the institution of a twenty-four hour physicians' telephone service at a local hospital or a physicians' exchange to provide for substitutes and for night calls. A little publicity and co-operation on the part of the local profession will assure the successful operation of the plan. The Council on Medical Service and Public Relations of the Wisconsin State Medical Association has recently

asked all component societies to take such action immediately.

The personal relationship between the patient and his physician constitutes the charm of private practice, and the scientific side of medicine or financial return must not be allowed to spoil that relationship.

EXPERIENCE WITH NITROGEN MUSTARD AND URETHANE IN THE LEUKEMIC STATES

THE use of nitrogen mustard as a therapeutic agent for lymphoblastoma and other neoplastic diseases is suggested by the fact that its qualitative effects are similar to, or identical with, those produced by roentgen rays or other types of irradiation. In experimental work, it was demonstrated that relatively small doses of the mustards could inhibit mitosis in actively proliferating cells without exerting demonstrable effects on nonproliferating cells. Somewhat larger doses resulted in evidences of nuclear and cytoplasmic injury. Clinically, a course of treatment usually consists of four daily intravenous injections of the drug in a dose of 0.1 mg. per kilogram of body weight. The dose of nitrogen mustard which is therapeutically effective for most patients will be followed, in two to three weeks after its administration, by lymphopenia, granulocytopenia and thrombocytopenia. Moderate anemia also may occur.

This action on the hematopoietic system makes mandatory re-examination of the blood in the month following treatment. It seems obvious that the susceptibility of the bone marrow to the depressing action of nitrogen mustard varies considerably among different patients. The immediate toxic effects consist of nausea and vomiting, coming on within three or four hours after administration and persisting for several hours. These effects often diminish in severity during the course of injections. As a rule, a period of at least four to six weeks is allowed to elapse between successive courses of treatment.

In the treatment of lymphoblastoma, it has not yet been determined whether nitrogen mustard can best be employed as the sole therapeutic agent or an adjunct to irradiation. The qualitative clinical response of previously untreated patients apparently is identical with that produced by irradiation in similar cases. As is true of roentgen therapy in cases of lymphoblastoma, the effectiveness of nitrogen mustard tends to diminish as repeated courses are administered.

In cases of Hodgkin's disease of long standing, in which the lesions have become refractory to roentgen therapy, nitrogen mustard often results in transient subjective improvement and occasionally produces a remission; usually, however, it cannot be expected to delay significantly the progress of the disease. Lesions of Hodgkin's disease which involve nonlymphoid organs usually do not respond well to this treatment. In general, the results obtained in treatment of lymphosarcoma have been less satisfactory and more unpredictable than those obtained in treatment of Hodgkin's disease.

In treatment of mycosis fungoides and cutaneous lymphoblastoma, nitrogen mustard has proved to be a valuable adjunct to irradiation therapy. Further remission of these conditions may be produced by nitrogen mustard after the lesions have become more or less refractory to the effect of roentgen rays. The two forms of therapy combined may well be effective where either alone is inadequate.

In treatment of malignant neoplasms other than the lymphoblastomas, some transient improvement has been obtained in cases of bronchogenic carcinoma. The outlook for the patient who has an inoperable lesion of this kind, however, has not been altered by introduction of nitrogen mustard therapy. Other malignant lesions have responded poorly or not at all to this agent.

The effect of nitrogen mustard on patients with chronic myelogenous leukemia or chronic lymphatic leukemia has been noted to be about equal to what might be expected from roentgen therapy under similar clinical conditions. Significant improvement cannot be expected in cases of acute leukemia.

Some encouraging initial results have been obtained in cases of polycythemia vera following nitrogen mustard therapy. It is believed that, as in leukemia, the effects may be shown to be at least as good as those obtained with irradiation.

The introduction of nitrogen mustard has opened a new and interesting field in therapeutics. First, the agent apparently exerts the same qualitative effects on tissues as does irradiation but is comparatively inexpensive and easily administered. Second, methyl-bis (beta-chloroethyl) amine hydrochloride, which is the nitrogen mustard most

frequently used clinically, is only one of a large family of similar compounds, and it is hoped that continued investigation will bring to light an agent of this type which will be therapeutically effective without exertng the undesirable toxic effects to which reference has been made. Meanwhile, much remains to be accomplished in the way of clinical investigation to determine what may be expected, under given clinical conditions, from the compounds now available.

In investigations of the action of urethane (ethyl carbamate) on tumor-bearing animals, it was incidentally found that in many cases there was a decided decrease in the number of leukocytes. This resulted in the therapeutic trial of this material in cases of leukemia, lymphosarcoma and allied diseases. It has been observed that normal leukocytes are more refractory to urethane than are leukemic cells. The mode of action of urethane is not understood, but it appears, on the basis of studies to date, that the action is associated primarily with inhibition of mitosis of immature cells.

Urethane has been used for too short a time to permit the formation of any definite conclusions as to its efficacy in leukemic states. This material does produce, in chronic forms of leukemia, palliative changes that are more or less constant. In acute forms of leukemia, little or no benefit is obtained from use of urethane, although the number of leukocytes in the peripheral blood may become rather rapidly reduced and a tendency for some maturation of immature forms may become evident. However, studies of the bone marrow have shown little if any change in the degree of immaturity. The clinical process continues to be acute and in no way is there sufficient change to warrant the use of urethane on other than an experimental basis in acute leukemia. On the other hand, the course of the chronic leukemias is somewhat modified by administration of urethane and the response of chronic myelogenous leukemia is better in general than that of chronic lymphatic leukemia.

Among different patients, there is great variation in tolerance to the drug and in the rapidity with which immature cells disappear from the peripheral blood. In some cases, relatively small doses of the drug—45 grains (3 gm.) administered daily for eight or nine days—will result in rapid remission; the blood will appear to be practically normal and there will be a parallel decrease in the degree of immaturity of the cells in the bone marrow. In other cases the response will be slow and a dose of 90 grains (6 gm.) daily for several weeks may be required to bring about remission.

An occasional person will prove to be unable to stomach the drug but usually, if the initial dose is small, 30 to 45 grains a day, untoward gastrointestinal reactions are minimal.

Chronic lymphatic leukemia has not responded particularly well to urethane although an occasional patient may experience a satisfactory remission. The same observation applies to patients with chronic leukemic reticulo-endotheliosis. Experience in cases of chronic myelogenous leukemia indicates that administration of urethane will control the disease fairly well hematologically and clinically, although there is no evidence that use of the substance will prolong life. With a small daily dose of urethane, the leukocyte count in most cases can be kept at a fairly satisfactory level (around 20,000 leukocytes per cubic millimeter of blood) for long periods. However, in spite of this, somewhat fulminating leukemia has developed in an occasional case, as evidenced by the character of cells obtained from the bone marrow on sternal aspiration. Interestingly, the picture found in the peripheral blood remains characteristic of a relatively chronic condition in these cases. Experience at Rochester has been that patients have progressively failed and have died with all the clinical evidence of fulminating leukemia.

Because of the convenience in administration of urethane, it offers definite advantages in palliative treatment or attempted control of the disease, but careful observation of the patient should be carried out at intervals of two weeks to a month and, if any elevation of temperature or other unexplained change in the general appearance of the patient should develop, administration of the drug should be discontinued. These, in our experience, may represent early signs of an acute change in the leukemic process. Sternal aspiration at such a time should be performed to confirm the diagnosis.

At present, in cases of chronic leukemia, palliation of symptoms can be obtained by use of various substances, but there is little evidence to date that such palliation greatly prolongs the life of a given individual. Occasional patients with chronic leukemia have, for various reasons, failed

to receive definitive treatment but have lived for relatively long periods, with few symptoms. Similarly, the clinical course of some persons who have received treatment at relatively infrequent intervals has been surprisingly satisfactory. Such instances must represent variations in the natural history of the disease processes concerned. Without a large control series of untreated patients, it does not seem justified to state that any known treatment significantly prolongs the life of the patient who has chronic leukemia.

C.H.W.

EWING'S PROPAGANDA FOR NATIONAL HEALTH INSURANCE

Recently Federal Security Administrator Oscar Ewing spoke before the convention of State and Territorial Health Officers in Washington on "The Job Ahead." Mr. Ewing said that national health insurance was the keystone to his proposed health plan.

Mr. Ewing said in part:

"Success (of the government health plan) depends on what the people themselves are willing to do about it.

"For that reason we must start laying the groundwork now. Every community must organize its own committees to analyze the plan in relation to its own community resources and community needs. These committees must establish liaison with similarly organized state groups under your leaderships charged with coordinating these resources and meeting demonstrated needs in a state-wide program.

"Equally important is the need to start, now, a state and local campaign of education to explain the scope and purpose of the plan and to demonstrate what it will mean to the health and well-being of every citizen of the community—to rally all business, professional and civic organizations, together with the churches and the labor unions, for an all out effort to start the ball rolling.

"To set such a project in motion requires responsible state and local leadership. It requires the unstinted faith and determination of men and women who can spearhead such a campaign and carry it through to a successful conclusion.

"I am putting this up to you, as an organization and as individuals, to undertake this responsible job. We are set to go on the most comprehensive program of health that has ever been offered to the people of the United States.

"If we all put our shoulder to the wheel we can translate this program into a living reality. And with the facilities we shall be able to command we shall create a standard of health and well-being for the entire country, such as no nation has ever dreamed."

Those six paragraphs from Mr. Ewing's talk are a clear-cut indication that the Federal Security Administration is going to the communities and people direct in its fight to put through a compulsory sickness insurance program.

Read Mr. Ewing's pleas again. Every sentence can be applied to the medical profession, aimed, of course, at educating the people to the dangers of compulsory sickness insurance. Every state and county medical society can take a lesson from Mr. Ewing's remarks and apply them to their own job ahead.

Mr. Ewing says that "success depends upon what the people themselves are willing to do about it." How true! That applies just as well in our fight.

Again, Mr. Ewing says that "to set such a project in motion requires responsible state and local leadership." Again, how true! The medical profession already has that leadership in state and county societies.

In his plea to get to the grass roots, Mr. Ewing urged his own workers to put their shoulders to the wheel. We must do that, too, within the states and counties of the nation so that the people everywhere will realize that any form of compulsory sickness insurance will necessitate a new payroll tax and the addition to the public payroll of thousands of administrative workers. We must push our 10-point program. Our job is, to put it in Mr. Ewing's words, "a state and local campaign of education," too. Only, we must stress the fact that the government isn't going to give the people anything for nothing because the government itself cannot produce wealth.

Urges Change of Tax Law to Favor Doctors

Self-employed professional men, such as lawyers and physicians, are discriminated against by our present federal income tax laws according to Frank G. Dickinson, Director of the AMA Bureau of Medical Economic Research.

Speaking at the Medicolegal Symposium of the Chicago Bar Association recently, Dr. Dickinson pointed out that the federal income tax laws permit self-employed individuals to use tax free funds to purchase pensions for their employes but not for themselves. Such employer contributions are subject to tax when the employe receives the pension but are not taxable to the employe during his working years when the employer is making the contribution.

Thus, many company doctors and company lawyers, who are employes, can look forward to pensions for their retired years. But the lawyer or doctor in private practice cannot use any tax free funds to finance a pension for himself or his partners.

"This feature of our tax law demands that a professional man incorporate himself in order to get the same privilege that a professional man or any other employe of a large firm can enjoy," said Dr. Dickinson. "The trouble is that most professional men cannot or will not incorporate. Many top management executives of corporations can look forward to five figure pensions when they retire in addition to the small pension provided by Social Security."

A movement, he explained, is now underway to get the federal income tax law amended to include physicians, lawyers and other professional people. It is hoped that the next Congress will take up legislation to eliminate this discrimination against self-employed professional people, including 99 per cent of the physicians who are engaged in private practice.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

AMA UNANIMOUS ON PLANS TO DEFEAT SOCIALISM

Accepting the fact that some form of socialized medicine will be proposed in Congress very soon, but refusing to accept the inevitability of its passage, the American Medical Association's House of Delegates, in Interim Session at St. Louis, Missouri, voted unanimously to build up a 3½-million-dollar educational fund.

The money will be used to "guide a nationwide plan of education on the progress of American medicine, the importance of conservation of health and the advantages of the American system in securing a wide distribution of high quality medical care."

Thus begins one phase of the fight to keep socialism from diluting American democracy. Money is needed because money makes possible the dissemination of facts. These facts must be cemented into a defense to blunt the edges of the weapons being used by the propagandists, notably those on the federal security payrolls.

The American people must become acquainted with the unvarnished side of the health-for-everybody-for-free plan. Ewing and his Utopia-painters and legislators of the Wagner, Murray, Dingell stamp have been hard at work for a long time, following a familiar pattern of mass psychology: establish the need, dress up the product to fit the need, sell by repetition.

Selective service rejection rates from World War II are the most recent tool to fall into the hands of the propaganda artists. By lumping together all reasons for rejection, including illiteracy and underweight, counting successive rejections for a selectee as separate rejections, failing to figure into the percentages the number of draft age men who volunteered for service, the ism-men turned what was really a tribute to the progress of American medicine and a demonstration of its universal availability into a condemnation of the profession and the present system of medical care.

This is typical of the "message" which federal tax funds are being used to carry. The refutation, when it came, was tardy and inadequately publicized. Dr. Maurice Friedman of Washington, D. C., exposed the misuse of the statistics, which were never intended as a survey of the nation's health or of the health of any segment of the population, anyway. But too many people received the first message, not the latter one. Cases like this show that "good news is no news," the reverse of the old wheeze, is almost always true and a factor to be reckoned with. The medical profession can't expect to make headlines with such information as "The United States has good medical care"; whereas, Ewing and Falk gain columns for their cause by misquoting and falsifying various studies of sickness and health and the availability of doctors and hospitals to give the two-fold impression that:

1. The health of the nation is bad, because
2. Too many of its inhabitants cannot afford medical care.

The truth is that the health of the nation is good, better by comparison than any other nation of similar size and heterogeneity of population. That compulsory health insurance, federal medicine, or whatever alias socialized medicine uses, would make the health of the nation better is untrue and must be constantly refuted by every possible means.

What would happen is easy to visualize: in the first place, taxpayers would be staggered by the extra assessment for universal medical care; doctors would be unable to cope with the increasingly large number of malingerers and chronic complainers who would wend their way daily to the doctors' offices; hospitals would be filled with them too so that emergency cases would not receive the immediate attention that they warranted; bureaucrats on the federal payroll would multiply with unprecedented speed as the

maze of report-filing, complaints, suits, charges and counter charges grew in complexity.

From socialized medicine, it would be an escalator ride to completely socialistic government.

These are the facts the people must have. They must be repeated over and over again. Scientific medicine has assumed its natural role of responsibility to convey these facts to people of every age, income, race, creed and color. This will take money. But the price tag on socialism makes the $25-per-doctor assessment look paltry indeed. For socialism would not only drain the people's financial resources, but their heritage of freedom as well.

There is another aspect to this problem also. Every doctor, aware of the implications of socialized medicine, probably wonders at some time or other how the whole fantastic scheme gains credence anywhere. The answer may be found in the doctor's own office, when he treats his patients brusquely, fails to explain their ailments or, when he explains them, does so in scientific language which the lay person does not understand. The answer may stem from his unexplained refusal to answer night calls or to care for a man with a heart attack because he is not a heart specialist. It may come from excessive charges, fee-splitting or unethical practices of various sorts.

Certainly it remains evident that far too many lay persons are being enthralled by the glib words of the government medicine merchants and while scientific medicine has made a strategic move in planning the educational campaign it has, still it is the responsibility of the individual doctor to serve not only as a physician, but as a public relations representative for his profession.

BLUE CROSS-BLUE SHIELD PLANS NEGATED BY AMA

Blue Cross-Blue Shield proposals for (1) association and (2) formation of a national insurance company were rejected by the American Medical Association's House of Delegates after thorough investigation and study.

The problems which brought forth these two suggestions, however, were recognized by the House and a substitute plan of action was agreed upon. Formation of a national enrollment agency and further development of co-ordination and reciprocity among the local plans was voted. It was generally felt that this system would facilitate the work of these two organizations and would dispatch the problems which have arisen, among them the difficulty of enrolling employes of national corporations, whose managements seek uniform contracts.

Rumors growing out of the discussions in the House indicated that AMA, in failing to adopt the ideas put forward by Blue Cross and Blue Shield leaders was refuting the entire Blue Cross-Blue Shield program. Evidence that this is not true is the action taken by the House in reaffirming the authority of the American Medical Association's Council on Medical Service to promote the voluntary prepayment medical care plan movement in America.

HARNESS ADVOCATES MORE POLITICAL ACTION BY DOCTORS

Forest A. Harness, chairman of the House Committee on Publicity and Propaganda, participated in a symposium on medical legislation during the AMA Interim Session and had this to say about doctor participation in politics:

"At the academic level, I know medical people have made tremendous efforts, both to resist the encroachments upon free institutions, and to meet the growing threats to your own profession. . . . But what effective effort has the profession ever made at the practical level? How much time, effort and substance have you ever devoted to everyday, down-to-earth, shirt-sleeve politics? Can you recall a single instance when the profession, or significant numbers within it, vigorously endorsed and supported a political party, or individual candidates? . . . Try to adjust your thinking to the inescapable fact that trends are not started or stopped in council chambers, but on street corners. Efforts expended at academic levels, and possibly directed to Congress at a given time, may speed or retard a trend. But if the efforts are to be permanently effective, they must reach the masses who write the decisions each two years in national elections.

"I think it is a great pity that people like you, who are best fitted by ability and training to provide leadership, have remained aloof. I think it is particularly regrettable that our medical people, who enjoy positions of confidence and trust hardly equalled by any other group in the American community, have so far neglected to prescribe for the body politic as part of their daily ministrations."

GRASS ROOTS CONCEPT ACCLAIMED AT SESSION

The Grass Roots conference, held November 30 as part of the AMA Interim Session, to "develop a working partnership between the American Medical association and every physician," was devoted mainly to the consideration of two problems: the relation of the doctor to national

preparedness and the roles of doctor and public in the socialized medicine system.

Military, civilian and medical viewpoints were expressed and it was the consensus of opinion that the armed forces are relying on the "responsibility of the doctor" to make a special draft of physicians unnecessary. The philosophy of service which is inculcated in every physician has been well demonstrated in war as well as in peace and possibility of induction of physicians by way of selective service seems remote.

In the second half of the evening's discussion, Dr. Maurice Friedman of Washington, D. C., amplified his study of the selective service rejection figures, noting dryly, "Mr. Ewing has made so many statements that, statistically, it would be impossible if some of them were not true."

Giving examples of the Ewing formula, Friedman pointed out that any set of figures, real or imagined, suits Mr. Ewing's purposes. It is an accepted fact that health studies by counties are impractical—sparsely populated counties with access to hospitals in adjacent counties could not support and have no real need for hospitals within the actual county boundaries, yet Ewing uses the fact that a number of counties in each state do not have hospitals as a selling point for compulsory health insurance.

Ewing asserts again and again that the mortality and morbidity rate in the United States could be slashed to almost nothing if only the people, all the people, had money enough to buy medical care or, rather, that this medical care was furnished them by the government. But Friedman has ably demonstrated by comparison that the mortality rate has no direct connection with the availability of medical care.

Ewing reasoning follows this line, Friedman declared: In the U. S. among white births, the mortality rate for males is 41.2 per 1000 live births. For females, it is 32.4. Therefore, male babies cannot afford proper care and are being discriminated against by the selfish, greedy medical profession!

AMA PASSES RESOLUTION ON REBATE QUESTION

Guided by the recommendation of the reference committee on miscellaneous business, the House of Delegates at St. Louis adopted the following resolution concerning rebates:

"Your committee has given prolonged consideration to this matter and approves that portion of the report which states that the House of Delegates reiterates condemnation of the practice of any member accepting rebates, and that the House of Delegates condemns also the practice of giving rebates by a member. It urges that the different state societies in those states in which such practices are not now illegal give serious consideration to the introduction of legislation making the practice of rebating to or by physicians illegal.

"Your committee recommends further to the component county societies that on the receipt of a bona fide complaint the disciplinary committee of that society should hold a hearing and endeavor to make an investigation of the doctor's records and accounts at society expense, and that a record of such hearings and examination should be kept for the information of the state society and, if necessary, for the Judicial Council of the American Medical Association."

WORLD WAR THREE BEGINNING IDENTIFIED

If there is a third World War, the day of the attack already has an identifying label, according to Brig. Gen. George E. Armstrong, deputy surgeon, General Department of the Army, Office of the Surgeon General. The day will be known as "C-Day"—Catastrophe Day.

Plans are being made to decentralize the military command and to make local units, including those assigned to civilian medical care, autonomous.

SOUTH CAROLINA DOCTOR GETS GP AWARD

Dr. W. L. (Buck) Pressly, Due West, South Carolina, general practitioner for thirty-two years, received the AMA General Practitioner award at the St. Louis meeting. Dr. Pressly, sixty-one, is considered an authority on rural health and sanitation in his state.

"In entering the medical field, I resolved and have sought rigidly to adhere to one idea—that my life would be one of service to mankind," said Dr. Pressly in accepting the award.

Nominations for the award came from twenty-three states. "All twenty-three nominees were distinguished general practitioners, noted in their respective states for their long and devoted service," said Dr. E. L. Henderson, chairman of the Board of Trustees.

Medical services are not commodities that can be bought in standardized packages wherever and whenever one has the money to pay for them.—Medicine in the Changing Order, Rep. New York Academy Med. Comm., The Commonwealth Fund, 1947.

Minnesota Academy of Medicine

Meeting of October 13, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 13, 1948. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 by the President, Dr. T. A. Peppard.

There were forty-eight members and five guests present.

Minutes of the May meeting were read and approved.

The scientific meeting following.

Dr. Vernon L. Hart, of Minneapolis, gave an interesting talk on a recent trip to Germany with three other medical men from the United States who went to Europe at the request of the Surgeon General to provide some setup for the young physicians from this country who are now located in hospitals in Germany.

Dr. Wesley Spink, of the University of Minnesota Medical School, read his Inaugural Thesis on the use of aureomycin, an abstract of which follows.

INVESTIGATIONS WITH THE ANTIBIOTIC AUREOMYCIN

(Abstract)

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

Aureomycin is an antibiotic isolated by Duggar of the Lederle Laboratories from *Streptomyces aureofaciens*. This antibacterial agent is a yellow crystalline material which is stable in this form, but its activity is rapidly lost when placed in solution. Of particular clinical interest, is the fact that the material is absorbed from the gastrointestinal tract following oral administration. Initial clinical investigations in human beings indicate that aureomycin induces only mild toxic reactions such as nausea, vomiting and soft stools.

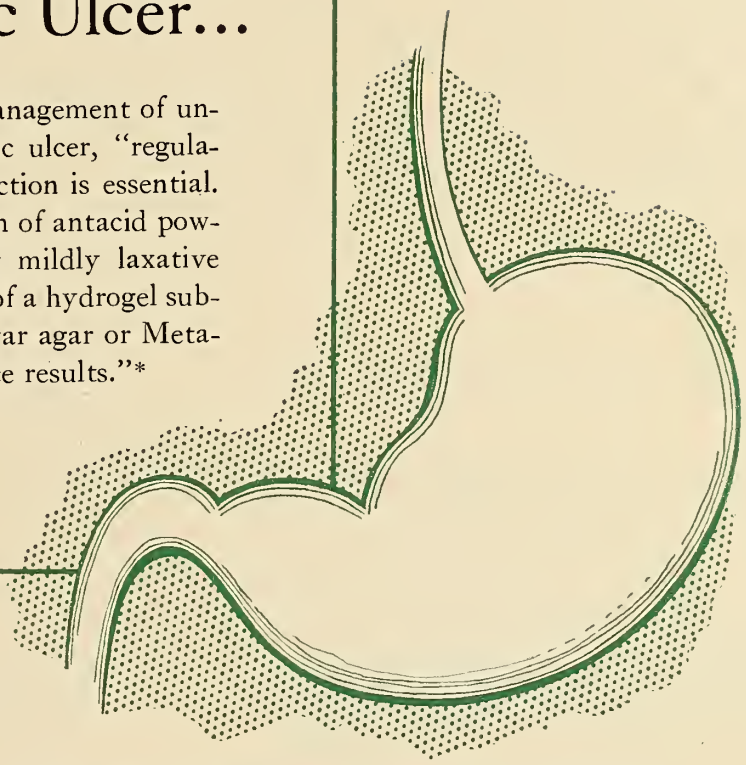
Aureomycin has a broad spectrum of antimicrobic activity being effective *in vitro* against Gram-positive organisms such as streptococci, staphylococci and pneumococcic; against the Gram-negative bacteria, *E. coli, Aerobacter aerogenes, Salmonella, Klebsiella pneumoniae, Neisseria, E. typhosa, Brucella* and *Hemophilus influenzae*. Most strains of *Proteus* and *Pseudomonas* appear to be resistant to aureomycin. The drug has proved to be quite active against the rickettsiae, which are the cause of the human diseases: murine and epidemic typhus, Rocky Mountain spotted fever, scrub typhus, Q fever, and rickettsialpox. And lastly, aureomycin inhibits the propagation of certain of the larger viruses including lymphogranuloma venereum, granuloma inguinale and psittacosis.

Up to the present time, aureomycin has been administered orally in capsules in doses of 0.5 to 1.5 gram every six hours. A salt of aureomycin may be given intramuscularly in aqueous solutions in total daily doses up to 200 mgs. This amount is divided into three or four doses. Solutions of aureomycin may be used topically, especially for ocular infections.

The actual status of aureomycin in human infection must await further studies. The following preliminary statements may have to be modified in the future. In the treatment of gonorrhea, a single oral dose of aureomycin is followed by a lower percentage of cures than is obtained with a single intramuscular injection of 300,000 units of penicillin. The response of patients with pneumococcic pneumonia to aureomycin has been encouraging. Thus far, the results in the treatment of uncomplicated cases of typhoid fever have not been remarkable. This also applies to disease caused by Salmonella. Urinary tract infections due to Gram negative organisms have been eradicated with aureomycin with the exception of disease due to *Proteus* and *Pseudomonas*. It would appear that aureomycin is the drug of choice for the therapy of lymphogranuloma venerum, and possibly, granuloma venerum. The antibiotic has yielded encouraging results in the treatment of Rocky Mountain spotted fever and Q fever. According to Braley and Sanders the local application of solutions of aureomycin to the eyes has been followed by good results in the treatment of staphylococcic blepharitis with conjunctivitis and keratitis; pneumococcic and influenza conjunctivitis and kera- infections due to the Morax-Axenfeld diplobacillus. Encouraging results have been obtained in the therapy of viral diseases of the eye including dendritic keratitis and inclusion conjuctivitis. The drug merits trial in trachoma.

At the University of Minnesota Hospitals, investigations have been under way during the past six months with Doctors Yow, Magoffin and Braude relative to the value of aureomycin in the treatment of brucellosis. Previous to these studies it had been established that the most satisfactory specific therapy was a combination of streptomycin and sulfadiazine. It has been of interest to observe that in comparing streptomycin with aureomycin for antibrucella activitiy, *in vitro* studies showed the former to be superior to aureomycin. Furthermore, in experimentally infected chick embryos, aureomycin did not afford as good protection as streptomycin. It is too early to draw any final conclusions on the value of aureomycin in the treatment of human brucellosis. A cooperative study on therapy in brucellosis is being carried out with Dr. M. Ruiz Castaneda in Mexico City. To date, it would seem that the oral administration of aureomycin is an exceedingly effective drug for this disease.

In summary, aureomycin is an antibiotic having a wide antimicrobic spectrum. It may be administered orally, and it has induced only the benign toxic reactions. For these reasons, intensive studies in human infections are warranted.



Discussion

Dr. R. T. LaVake, Minneapolis: I would like to ask Dr. Spink if blood transfusion has been used as an

(Continued on Page 92)

Bowel Regulation in Peptic Ulcer...

In the medical management of uncomplicated peptic ulcer, "regulation of bowel function is essential. . . . A combination of antacid powders . . . having mildly laxative effects or the use of a hydrogel substance, such as agar agar or Metamucil, will produce results."*

By furnishing a water-retaining, gelatinous residue in the large bowel, Metamucil acts gently without irritation to promote smooth, normal evacuation.

METAMUCIL®

is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent.

MINNESOTA ACADEMY OF MEDICINE

(Continued from Page 90)

adjuvant in these cases. When we first began the use of the sulfonamides in infections, in several cases when no beneficial results were obtained, multiple transfusions rapidly changed the whole picture for the better.

Dr. L. Logan Leven, Saint Paul: I am greatly impressed with the results of aureomycin as presented by Dr. Spink tonight. I had the opportunity to see its effect on a badly burned patient on my service at the University Hospital. This child had extensive, badly infected burns. She had developed a pyemia and had osteomyelitis of the mandible as well. She was given the usual therapy for this type of case. She was sensitive to sulfonamides and to penicillin. About the time that all therapy seemed hopeless, aureomycin was used, and a sudden improvement was noted. The temperature returned to normal, and the patient was promptly gotten into condition for skin grafting. The result in this case was most striking.

Dr. F. W. Lynch, Saint Paul: Dr. Spink listed a variety of organisms sensitive to this drug. Are we to understand that most of the other common organisms are not sensitive, or have they not yet been tried?

Dr. Spink, in closing: An answer to Dr. LaVake's question about the use of transfusions with antibiotics, there is no specific advantage in giving either whole blood or plasma with any of the antibiotics. Transfusions should be employed when there are clear-cut indications for their use such as anemia, hypoprotinemia and shock. In fact, I am exceedingly apprehensive about the indiscriminate use of blood transfusion, because of the potential danger of severe and fatal reactions. Furthermore, infusions with pooled plasma are associated with the danger of inducing homologous serum hepatitis. It is of historical interest that immune serum appeared to be an effective agent for the treatment of infections due to Group A hemolytic streptococci, and if the sulfonamides and antibiotics had not been introduced at the time, immune transfusions would have been widely used in the treatment of streptococcic disease, especially puerperal sepsis.

In answer to Dr. Lynch's question, undoubtedly other species of micro-organisms are sensitive to aureomycin. I should like to emphasize that our primary interest in this antibiotic has been with relation to brucellosis. Such observations that have been made in our laboratory with other diseases and bacteria are an outgrowth of this major interest. Although tremendous advances have been made in the management and control of infectious diseases there is still room for improvement. There is probably no more satisfaction in the whole field of medicine than that which is obtained in treating successfully, infectious diseases which only a few years ago were considered highly fatal diseases. Consider the previous mortality rate of 80 per cent for staphylococcic septicemia, compared to a present rate of less than 20 per cent; of 100 per cent for pneumococcic meningitis, compared to a present rate of at least less than 50 per cent; of subacute bacterial endocarditis with its previous death rate of around 100 per cent, and now a recovery rate of over 75 per cent.

However, as I have stated previously, there is still room for improvement and that is why a continued interest will be manifested in antibiotic therapy.

The meeting adjourned.

A. E. Cardle, M.D., *Secretary*

In Memoriam

PIERRE C. PILON

Dr. Pierre C. Pilon of Paynesville, Minnesota, died on December 16, 1948. He was eighty-four years of age.

Dr. Pilon obtained his medical degree from the University of Victoria, May 12, 1886, and began practice at Cold Spring. Later he moved to Richmond, Minnesota. In 1897 he moved to Paynesville and for a time was a member of the Stearns-Benton County Medical Society.

As a major in World War I, he was superintendent of an auxiliary base hospital at Bordeaux, France.

In 1936 Dr. Pilon was honored at a testimonial dinner given him by one hundred and fifty friends, commemorating his fifty years of practice. The same year he and Mrs. Pilon returned to France to visit friends and relatives.

Dr. Pilon had served as mayor of Paynesville, coroner of Stearns County and as a member of the Minnesota State Board of Medical Examiners.

He is survived by his widow and a brother.

THE CANCER PROBLEM

(Continued from Page 69)

due solely to metastatic carcinoma and was in no way attributable to the operation. There were no other hospital deaths in this series.

Summary

The problem of cancer diagnosis and treatment has been discussed from the standpoint of the practicing physician in a small community and the role of the practicing physician in the reduction of cancer mortality has been stressed.

A small series of cancer cases from the author's practice has been presented as a basis for this discussion. A composite analysis of similar series of cases from many other smaller communities throughout the state should be made in order to evaluate the average practicing physician's abilities and shortcomings in the diagnosis and treatment of cancer.

adequate facilities and personnel are available. Merely taking the smears and submitting them to the laboratory, where no adequate provisions are available, would not be just either to the patient or the technique.

It is clearly the responsibility of the pathologist to accept the Papanicolaou method as an aid in cancer diagnosis, and to guide the medical profession in its judicious use, by impressing upon its members the fact that the method, while it has proven its value in cancer diagnosis, is actually often more difficult, is time-consuming, and lacks definitiveness that the biopsy more easily affords. All this means special training for practicing pathologists.

AT HOME OR AWAY **SPOT TESTS** SIMPLIFY URINALYSIS

No Test Tubes • No Measuring • No Boiling

Diabetics welcome "Spot Tests" (ready to use dry reagents), because of the ease and simplicity in using. No test tubes, no boiling, no measuring; just a little powder, a little urine—color reaction occurs at once if sugar or acetone is present.

Galatest . . . Acetone Test (DENCO)

FOR DETECTION OF SUGAR IN THE URINE

FOR DETECTION OF ACETONE IN THE URINE

SAME SIMPLE TECHNIQUE FOR BOTH

1. A LITTLE POWDER
2. A LITTLE URINE

COLOR REACTION IMMEDIATELY

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The case also contains a medicine dropper and a Galatest color chart. This handy kit or refills of Acetone Test (Denco) and Galatest are obtainable at all prescription pharmacies and surgical supply houses.

Accepted for advertising in the Journal of the A.M.A.

NATIONAL CONFERENCE ON MEDICAL SERVICE

Palmer House, Chicago, Illinois, February 6, 1949

Morning Session—9:00 A.M.

Registration: Foyer of Red Lacquer Room Fourth Floor Palmer House.

Appointment of Committees.

Address of the President—E. F. Sladek, M.D., Traverse City, Michigan.

Legalized Medical Research.

Medical Problems.—Chris J. D. Zarafonetis, M.D., University of Michigan.

Legal Problems.—George Wakerlin, M.D., University of Illinois.

Title to be announced.—James R. McVay, M.D., Kansas City, Missouri; Chairman, Council on Medical Service, AMA.

Progress of the World Health Organization.—Frank Calderone, M.D., Director, American Office, World Health Organization.

Progress of the World Medical Association.—Creighton Barker, M.D., Executive Secretary, Connecticut State Medical Association.

Medical Program of the United Mine Workers of America Welfare and Retirement Fund.—Warren F. Draper, M.D., Executive Medical Director.

Subscription Luncheon—12:15 P.M.

Afternoon Session—1:00 P.M.

The AMA puts on its Fighting Togs.—(Speaker to be announced.)

What's Happening in Washington This Week.—James D. Boyle, United Public Health League.

Discussion—To be opened by Joseph S. Lawrence, M.D. Director of the Washington Office, AMA.

Panel Discussion on Postgraduate Education of the Doctor.

(a) Responsibility of Medical Schools in Continued Postgraduate Education of the Doctor.—George N. Aagaard, Director of Postgraduate Medical Education Program, University of Minnesota.

(b) Function of the State Medical Society in Postgraduate Work.—C. W. Smith, M.D., Harrisburg, Pennsylvania.

(c) Survey Findings on Specialization in Colorado.—Harold I. Goldman, M.D., Denver, Colorado.

Can Corporations Such as Hospitals Legally Engage in the Practice of Medicine?—Wilbur Bailey, M.D., Los Angeles, California.

Report of Committees and Election of Officers.

Physicians are urged to attend and take part in discussions.

POSTGRADUATE COURSE IN DISEASES OF THE CHEST

The Council on Postgraduate Medical Education of the American College of Chest Physicians and the Laennec Society of Philadelphia announce a Postgraduate Course in Diseases of the Chest to be held at the Warwick Hotel, Philadelphia, Pennsylvania, February 28 through March 5, 1949. This course will emphasize the recent developments in all aspects of diagnosis and treatment of diseases of the chest.

The course is open to all physicians, although the number of registrants will be limited. Applications will be accepted in the order in which they are received. The tuition fee is $50.00.

Application may be made through the Executive Offices of the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

RESEARCH FELLOWSHIPS

Announcement of the availability of ten research fellowships to be awarded for one year in the fields of medicine, dentistry, and pharmacy has been announced by the University of Illinois Graduate College in Chicago.

The fellowships carry stipends of $1,800 per year for medical and dental graduates and $1,200 for pharmacy graduates, with exemption from tuition fees for all appointees. Registration in the Graduate College for credit toward M.S. or Ph.D. degrees is required.

Candidates should indicate the field of research in which they are interested and submit transcripts of their scholastic credits, together with the names of three former science teachers as references. Appointments will be announced March 1, 1949, or shortly thereafter. The fellowship year begins on July 1, 1949, or September 1, 1949.

Formal application blanks may be secured from the Secretary of the Graduate Committee, 1853 W. Polk Street, Chicago 12, Illinois.

INFANTILE PARALYSIS FELLOWSHIPS

The National Foundation for Infantile Paralysis announces that a limited number of research fellowships are available in virology, orthopedic surgery, pediatrics, epidemiology, neurology, physical medicine and public health. Requirements for the appointments, which are sponsored by the Foundation, include medical training and two years of training at the residency level in the particular field.

Details may be obtained from the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, New York.

LET'S TALK ABOUT HEALTH

The following broadcasts will be given by Dr. D. A. Dukelow, Director of the Health and Medical Care Division of the Community Chest and Council of Hennepin County, in January and February.

1949

Jan. 3. Public Health Legislation.
Jan. 10. Winter Health Hazards.
Jan. 17. Our New Blood Bank.
Jan. 24. Allergy.
Jan. 31. Live longer and Like It.
Feb. 7. Saving Children's Teeth.
Feb. 14. Have a Heart.
Feb. 21. What Is Mental Illness?
Feb. 28. Report on Public Health Bills in Congress.

COURSES IN FOOD HANDLING

To help in protecting the public against food-borne diseases, courses for food handlers and other restaurant employes will be given at several centers by the Minnesota Department of Health during the coming year. These courses are given under the direction of the Division of Hotel and Resort Inspection, and are open free of charge to persons concerned in the handling of foods and drinks in hotels, restaurants, bars, schools, hospitals, and institutions.

The courses, each two hours in length, emphasize the points to observe in preventing outbreaks of food poisoning and the importance of personal hygiene and safe food handling and cleaning techniques.

The Division of Hotel and Resort Inspection was created by the State Legislature forty-five years ago, with the primary purpose of regulating the operation of inns and lodging houses. Since then this division has expanded its activities to include sanitary supervision of cabin camps, tourist homes, taverns, resorts, hotels, restaurants, and soda fountains.

At present the personnel of the division consists of a director, Mr. Harold S. Adams, also nine inspectors and five clerical workers. The division is responsible by law for licensing all the establishments named above. The law also makes it mandatory that an inspection be made at least once a year of all places under licensure. The inspectors check such aspects of food sanitation as refrigeration of perishable foods, proper food handling methods, safe storage and display of foods, dishwashing operations, locker and rest room sanitation, insect and rodent control. They also consider aspects of fire prevention and protection, including proper means of egress, condition of fire extinguishers and fire hose, removal of combustible materials, safe wiring and proper designation of exits by lights and signs.

Since there are more than 18,000 licensed establishments in Minnesota, it is evident that inspections cannot be made as frequently as would be desirable. However, the division can point with pride to much accomplishment in promoting safety and sanitation in hotels and other establishments throughout the state.

TWO CONTINUATION COURSES

The University of Minnesota announces a continuation course in cardiovascular diseases to be given at the Center for Continuation Study on February 14 and 15, 1949. The course is intended for general physicians and is sponsored by the Minnesota Heart Association.

The University of Minnesota announces a continuation course in pediatrics to be given at the Center for Continuation Study on February 7, 8, and 9, 1949. The course is intended for general physicians and is sponsored by the Minnesota Department of Health.

MINNESOTA SOCIETY FOR THE PREVENTION OF BLINDNESS

The annual meeting of the Minnesota Society for the Prevention of Blindness and Conservation of Vision was held at the Coffman Memorial Union at the University on December 14, 1948.

The meeting was presided over by Mr. Amos S. Deinard, president, who told of the purpose of the society, the prevention of eye accidents and the early treatment of eye diseases to conserve vision. The society has been sponsoring a state bill to prevent the sale of air rifles which are the cause of so many accidents to the eyes and which Mr. Deinard stated serve no useful purpose.

Miss Mary Davis, daughter of the late Dr. William Davis, was elected president for 1949.

GOODHUE COUNTY SOCIETY

The annual meeting of the Goodhue County Medical Society was held in Red Wing early in December, with election of officers highlighting the program.

Dr. G. W. Bagby, Cannon Falls, was elected president of the organization, succeeding Dr. M. G. Flom of Zumbrota. Other officers elected were Dr. L. E. Steffens, vice president, and Dr. J. F. Brusegard, secretary-treasurer, both of Red Wing. For the second successive year the society named Dr. M. R. Williams of Cannon Falls the outstanding general practitioner in the county.

RAMSEY COUNTY SOCIETY

At a meeting of the Ramsey County Medical Society in Saint Paul on November 29, Dr. Warner Ogden was named president-elect, to take office in 1950. Dr. J. R. Aurelius was installed at the meeting as president for 1949. Other officers elected were Dr. William A. Kennedy, vice president, and Dr. Laurence Hilger, secretary-treasurer.

SIOUX VALLEY MEDICAL ASSOCIATION

The annual meeting of the Sioux Valley Medical Association will be held at the Hotel Cataract, Sioux Falls, South Dakota, on January 25, 26 and 27. Plans for the meeting call for emphasis on subjects of primary interest to the general practitioner. All physicians are welcome to attend.

WASHINGTON COUNTY

The annual meeting of the Washington County Medical Society was held November 14, 1948. Officers elected for 1949 were: Dr. W. R. Humphrey, president; Dr. C. H. Sherman, first vice president; Dr. G. M. Ruggles, second vice president; Dr. E. S. Boleyn, secretary-treasurer (re-elected).

Members of the County Welfare Board met with the society and some disputed fees for attending hospitalized indigents were adjusted satisfactorily.

AMNIOTIC FLUID AND MECONIUM EMBOLISM

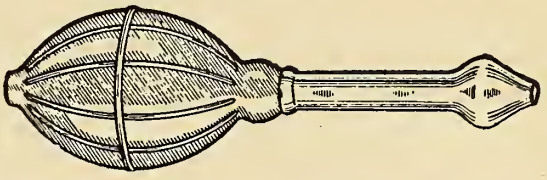
(Continued from Page 72)

epithelial squamae in the capillaries, arterioles and small arteries of less than 1.0 mm. in size in the lungs.

The autopsy report of the fetus in Case 1 is included in the paper because the death was attributed to the aspiration of the meconium-stained amniotic fluid. It is generally agreed that under conditions of severe asphyxia, violent fetal respiratory efforts occur, and that there is often an associated expulsion of meconium into the amniotic fluid. This apparently occurred in Case 1 where the asphxyia probably occurred as a result of the placenta previa. It may be further assumed that this asphyxia ultimately resulted in the death of both mother and child.

Summary

1. Two cases of maternal pulmonary embolism by meconium and amniotic fluid are reported.



2. In labor the fluid and meconium probably are forced into the uterine sinuses by the strongly contracting organ. The fluid can also enter the maternal circulation during cesarean section.

3. The particulate matter of the amniotic fluid, i.e., the meconium, vernix caseosa, lanugo hairs, and epithelial squamae are responsible for the embolic plugging of the pulmonary circulation.

Woman's Auxiliary

HYGEIA IN EVERY DOCTOR'S OFFICE WOMAN'S AUXILIARY GOAL

Mrs. C. L. Sheedy

In the past few years *Hygeia* has published more than 50,000 words on federalized medicine. What better way can we inform the public on such issues than by buying *Hygeia* for ourselves and making it known to others?

No consistent reader of *Hygeia* could be duped by quackery, either. *Hygeia* educates the patient to dispel unfounded fears by giving reliable, authentic health information in clear, concise and simple terms. *Hygeia* has published many articles stressing doctor-patient cooperation and education. These recent titles are indicative of *Hygeia's* role in the drama of health and sickness: "Doctors Guard Your Health," "Can Chiropractic Cure?" and "You Can't Doctor Yourself."

Surely the most logical place for the magazine is the physician's reception room. As early as 1920, the need for a health magazine was recognized by many physicians and two years later the American Medical Association's House of Delegates authorized its publication. In April of this year, *Hygeia* completed its twenty-fifth year of service to the public.

Designed for a lay public, the magazine contains interesting, informative material for those of the profession. Special rates make it possible for physicians and dentists and their families to receive the magazine at half its cost to the public—$1.50 per year, $2.50 for two years and $3.25 for three years. The regular subscription rate, however, compares favorably with other quality magazines of general circulation.

Traditionally, the Woman's Auxiliary is charged with the responsibility of promoting *Hygeia,* through Parent-Teacher groups, boards of education and similar organizations interested in health education. Unfortunately, the bulk of this work has been carried on principally by a small number of Auxiliaries. We have over 600 organized county units, but 90 per cent of the orders come from 25 per cent of the county auxiliaries; another 25 per cent showed interest, but more than 50 per cent took no part in the promotion of the magazine.

Minnesota has twenty-eight counties. Eight counties did not report a single *Hygeia* subscription last year. Let's redouble our efforts in behalf of America's greatest health publication. Let's make this Minnesota's biggest *Hygeia* subscription year.

AUXILIARY INFLUENCE MUST BE AN INFORMED INFLUENCE

Mrs. William Von der Weyer

At the beginning of the year, with all the enthusiasm of a new recruit, your Bulletin chairman determined to make every one of the 1,672 members in the State Auxiliary a subscriber to the *Bulletin of the Woman's Auxiliary to the AMA.* Inspired by the zeal of our president, Margaret Wahlquist, and with the desire to make hers a successful year, subscription blanks were sent to all County Auxiliary presidents, urging them to get new and renewed subscriptions. So far, only a few of these have been returned, but it is expected that many more will be coming in during the post holiday months.

If we, as doctors' wives, are to have any influence in health matters in our state, we must have *The Bulletin* as well as other health literature to help us inform our neighbors and friends as to medical legislation, new therapeutic practices, new medicines, new food products, the nursing situation, and many other subjects which are aids to human welfare.

Did you know that the number of Auxiliary members in the United States is almost 50,000? Think of the opportunity so many of us have of bringing our informative messages to 3.5 million members of other women's organizations throughout the nation! So *please* subscribe to *The Bulletin.* You'll be doing yourself a great good—just send your dollar to: Mrs. Wm. Von der Weyer, 601 Montcalm Place, St. Paul, Minnesota.

FALL BOARD MEETING

Mrs. W. A. Merritt

Three women were given regular appointments and three, special appointments, at the fall board meeting of the Woman's Auxiliary to the Minnesota State Medical Association, held September 25, in the Italian Room of the Radisson Hotel, Minneapolis, following the Auxiliary Workshop. The assignments are as follows:

Mrs. S. S. Hesselgrave, Parliamentarian; Mrs. E. V. Goltz, Advisory Committee; Mrs. Martin Nordland, Advisory Committee; Mrs. Walter Haven, Workshop Committee; Mrs. L. S. Arling, Newsletter; Mrs. Harold G. Benjamin, Roster.

Elected to the Nominating Committee were: Mrs. E. V. Goltz, Mrs. L. P. Howell, Mrs. A. Christiansen, Mrs. Henry W. Quist, Mrs. Hobart Johnson; alternates, Mrs. John Butler and Mrs. J. L. Bowen.

Attended by thirty-six officers and county presidents, the meeting went on record as endorsing the cancer essay and poster contests throughout the state, giving to these projects the sum allocated in the Auxiliary's budget for cancer and co-sponsoring the essay and poster contests.

Fifty dollars was earmarked for prizes for the state tuberculosis essay contests.

County presidents were reminded by Mrs. Harold W. Wahlquist, state president, to collect 25 cents per capita for the Dr. O'Brien Memorial Fund, in line with the Auxiliary vote last spring.

Mrs. S. S. Hesselgrave, parliamentarian, explained the increase in National Auxiliary dues to one dollar per member, the fund to be used for periodicals sponsored by the national Auxiliary when revenue justifies their publication.

Silent tribute was paid by the group to two deceased members of the State Auxiliary board: Mrs. James S. Reynolds and Mrs. James Blake, Sr.

Mrs. H. W. Wahlquist and Mrs. Luther H. Kice, national president spoke briefly, and reports were given by standing committee chairmen and presidents of county auxiliaries from: Blue Earth, Hennepin, Mower, Ramsey, Renville, Southwestern, Stearns-Benton, and Upper Mississippi.

NEWS NOTES FROM WASHINGTON COUNTY
Mrs. R. E. Carlson

Mrs. Ray Johnson, wife of Dr. Johnson of the state prison staff, died late this summer.

Mrs. E. Sydney Boleyn has been in the hospital since October 4 when she was struck by an automobile.

Mrs. Carrie Landeen has been confined to her bed for a month.

ST. LOUIS COUNTY NETS $306 FOR PHILANTHROPY
Mrs. P. S. Rudi

The annual rummage sale held by the St. Louis County Auxiliary boosted the group's philanthropic fund by $306. Budget expenses will be met also by the proceeds of the project.

Auxiliary members were dinner guests of the St. Louis County Medical Society, December 8. Dr. Vernon Smith of St. Paul was guest speaker and showed his wild game and skiing pictures. Dr. P. S. Rudie, retiring president, paid tribute to the Auxiliary and to the pioneer members of the Medical Society responsible for its growth and progress.

STEARNS-BENTON GROUP AIDS CANCER CLINIC
Mrs. R. C. Smith

Most recent project of the Stearns-Benton Auxiliary was assisting with the Cancer Clinic, held in St. Cloud December 4. Concurrently, the members are laying plans for: supplementing the loan fund for the nurses at the St. Cloud hospital, and arranging the program for the St. Cloud Health Day and many other activities.

WINONA WOMEN SEW FOR HOSPITAL THERE
Mrs. P. A. Mattison

Sewing for the Winona General Hospital is keeping the Auxiliary busy at its twice-monthly meetings. In addition to the sewing sessions, the Auxiliary held two other meetings recently, one devoted to Workshop reports and the other to discussions of medical legislations, led by Mrs. Elmer Rusten.

POSSIBILITIES UNLIMITED FOR HEALTH DAYS
Mrs. Hobart Johnson

Southwestern Auxiliary, comprising six counties, pioneered this year in the field of community Health Days, held in co-operation with the local medical society and the Minnesota Department of Health. The success

of this meeting led to the decision of the Minnesota State Medical Association and the Auxiliary to sponsor such Health Days in various parts of the state.

As public relations chairman, it has been my pleasure to attend subsequent Health Days and to note the part we play as an organization. The success of the meetings is somewhat in proportion to the amount of work that the wives of physicians have been willing to do, both in planning and publicizing.

In evaluating these Health Days as a continued project in our state and as a recommendation for other states, it is evident that the good results far outweigh the difficulties encountered. Speakers of high calibre can be approached, because they are assured of a representative audience. Many leaders will be present who will not only profit by the discussions but by personal contacts they make at such a time. Many new friendships are formed among the wives of physicians as they meet and work together for the good of the community.

Factors to be considered are:

Preliminary Plans.—Choice of date (fear of polio is prevalent in the early fall), counties to be included, subjects to be presented and by whom, publicity by the press and radio, letter and in person, with special emphasis that the general public is invited, chairman and committees, with special stress on co-operation of Auxiliary members.

Health Day Details.—Registration (desk must be located so that noise does not interfere with sessions), hospitality, handling of the crowd, provision for good loudspeaker system, timing of panels and speakers to sustain audience interest.

The November issue of MINNESOTA MEDICINE carried the Minnesota Department of Health endorsement of Health Days and the medical societies and auxiliaries owe the department personnel a debt of deep gratitude. It was also gratifying to see how many doctors attended the meetings and took part in the programs.

Auxiliary members can be proud of the accomplishments of this year and yet realize that the possibilities for good in this line of endeavor are unlimited. In the beginning, those with vision must work hard to lead the way, but year by year the links in our chain will grow stronger and because of our efforts the citizens of Minnesota will learn that the medical profession stands united to help show them the way to happier and healthier living.

Of General Interest

Dr. Edward Q. Ertel, Ellendale, was in Chicago during the middle of November attending a surgical convention.

* * *

Dr. Leslie Caplan has opened offices at 340 LaSalle Building, Minneapolis, for the practice of psychiatry.

* * *

During the middle of November Dr. Douglas L. Jacobs of Willmar attended a medical convention in Cleveland, Ohio.

* * *

Dr. Charles W. Rogers of the Winona Clinic attended a continuation course in pediatrics at the University of Minnesota early in December.

* * *

Dr. Norman Johnson, Minneapolis, announces the reopening of an office at 65 South Tenth Street for the practice of internal medicine.

* * *

Dr. and Mrs. W. F. Mercil, Crookston, were in Minneapolis during the middle of November while Dr. Mercil attended a medical meeting.

* * *

A semi-annual chest clinic was held in Owatonna on November 30 by Dr. Karl H. Pfuetze, director of the Mineral Springs Sanatorium at Cannon Falls.

* * *

Among those attending a meeting of the Scott-Carver County Medical Society in New Prague on November 24 was Dr. H. M. Juergens of Belle Plaine.

* * *

Among Minnesota men attending the interim session of the American Medical Association in St. Louis, Missouri, early in December was Dr. J. C. Jacobs of Willmar.

* * *

One of the speakers at the annual meeting of the Minnesota Association of Coroners in St. Cloud December 10 and 11 was Dr. James Cardy of the University of Minnesota pathology department.

* * *

"The Concept of a Healing Force in Medical Psychology" was discussed by Dr. Maurice N. Walsh, Rochester, at a meeting of the Minnesota Society of Neurology and Psychiatry in Saint Paul on November 9.

* * *

Principal speaker at a meeting of the Rotary Club in Hibbing on November 11, Dr. T. A. Estrem described changes in the practice of medicine in the past thirty years.

* * *

In November, Dr. N. N. Ninneman purchased a home in Waconia only two doors from his office quarters. It was announced that he planned to use the building both as office and as residence.

* * *

Dr. H. P. Rome, Rochester, has been appointed chairman of the training committee in psychiatry of the United States Public Health Advisory Board. The committee allots funds for the undergraduate and graduate training of psychiatrists throughout the United States.

* * *

Dr. Ralph E. Creighton, Minneapolis, was appointed on November 22 to the board of directors of the Minneapolis Community Chest and Council. Dr. Creighton is a past president of the Hennepin County Medical Society.

* * *

Dr. Waltman Walters, Rochester, was elected president-elect for 1949-1950 of the Interstate Postgraduate Medical Association of North America at a meeting of the group in Cleveland, Ohio, November 9 through 11.

* * *

The disadvantages of socialization of medicine were discussed by Dr. Martin O. Wallace, Duluth, when he spoke at a meeting of the Duluth Kiwanis Club on November 10.

* * *

Dr. Clyde A. Undine of Minneapolis attended the Midwest regional meeting of the American College of Physicians held in Detroit, Michigan, November 20, 1948.

* * *

Among Minnesota physicians attending a two-day continuation course in obstetrics and gynecology at the University of Minnesota November 15 and 16 was Dr. M. I. Howard of Mankato.

* * *

During the middle of November, Dr. and Mrs. L. W. Johnsrud of Hibbing were week end guests of former Hibbing residents, Dr. and Mrs. Randall Derifield, now living in Des Moines, Iowa.

* * *

Among those in attendance at a meeting of the Minnesota Surgical Society in Saint Paul on November 5 was Dr. Albert Fritsche of New Ulm. The society meeting was held at Ancker Hospital.

* * *

"Psychiatric Problems of Adolescence" was the topic discussed by Dr. Edward Anderson, Minneapolis, when he spoke at a meeting of the Blue Earth Valley Medical Society in Winnebago on October 21.

* * *

Principal speaker at the Armistice Day assembly of the Rochester senior high school was Dr. Maurice N. Walsh, of the Mayo Clinic, who spoke to students on the theme, "Safeguarding Our America."

* * *

In Crookston, Dr. C. G. Uhley spoke on cancer at a meeting of the Parent-Teacher Association of Washington School on November 15. Dr. Uhley is a director of the Minnesota Division of the American Cancer Society.

* * *

Dr. Robert M. Drake, son of Dr. Charles R. Drake of Minneapolis, is taking a fellowship in pediatrics at the Mayo Foundation. Dr. Drake was married to Miss Merry H. Ekblad last April.

Dr. Jack T. Murphy has become associated with Dr. Joseph M. Ryan in the practice of internal medicine with offices at 524 Lowry Medical Arts Building, Saint Paul. It was erroneously reported in the December issue that his association was with Dr. Joseph M. Riga.

* * *

"New Drugs and New Concepts in Medicine" was the title of a talk given by Dr. Harold G. Benjamin, Minneapolis, at a luncheon meeting of the Minneapolis Professional Men's Club early in December. He cautioned his audience that "each new drug has its limitations."

* * *

Dr. Philip F. Eckman, Duluth, was renamed chairman of the Duluth Chamber of Commerce public health committee, it was announced on November 17. The committee, composed of both physicians and laymen, deals with health problems from a community standpoint.

* * *

It was announced in November that Dr. J. W. Helland, Spring Grove, had been re-elected representative director of the Minnesota Public Health Association. Dr. Helland is president of the Houston County Public Health Association.

* * *

Included in the sixty Northwest physicians who attended a three-day continuation course in gastroenterology at the University of Minnesota in late October were Dr. Roy T. Pearson, Shakopee, and Dr. Harry Shragg, Elmore.

* * *

Dr. and Mrs. Carl W. Waldron, Dr. and Mrs. C. I. Karlecn, and Dr. and Mrs. S. G. Balkin, all of Minneapolis, were visitors in November at the Greenbrier, White Sulphur Springs, West Virginia, where the three physicians attended a meeting of plastic surgeons.

* * *

In an address before the Lions Club of Rochester on December 2, Dr. M. M. Hargraves discussed "The Real Objectives of the Izaak Walton League." The talk was given one week before Dr. Hargraves was to retire as president of the Minnesota league upon expiration of his term of office.

* * *

Three European medical groups honored Dr. Henry W. Meyerding, Rochester, during his recent stay in Europe. Dr. Meyerding was made an honorary member of the Netherlands Orthopaedic Association, the Czechoslovak Society of Orthopaedic Surgery and Traumatology, and the French Surgical Society.

* * *

It was announced on November 24 that Dr. Austin McCarthy, formerly of Minneapolis, had become associated with the Willmar Clinic. A graduate of the University of Minnesota Medical School, Dr. McCarthy interned at Minneapolis General Hospital and spent several years there as a resident in surgery.

* * *

Dr. Otto C. Phares, formerly of Minneapolis, has opened offices in St. Cloud at 701½ St. Germain Street. He is limiting his practice to urology. Dr. Phares recently completed a three-year fellowship in urology at Minneapolis General Hospital. He is a graduate of the University of Minnesota Medical School.

* * *

On November 18 the Davis Clinic of Wadena announced the addition of Dr. Thomas D. Moberg, formerly of Minneapolis, to its staff. A graduate of the University of Minnesota Medical School, Dr. Moberg served his internship at Waterbury Hospital, Waterbury, Connecticut.

* * *

Dr. F. N. Grose was named Clarissa's "man of the year" at the annual dinner held on November 11 by the Clarissa Commercial Club. Each year the award is given to the citizen who, in the opinion of the club, has contributed most to community development and progress. Dr. Grose has practiced in Clarissa for twenty years.

* * *

It was announced on November 17 that Dr. Charles E. Stafford planned to leave Baudette within thirty days to become head of the medical department of the veterans hospital at America Lake, near Tacoma, Washington. Dr. Stafford had practiced medicine in Baudette for several years.

* * *

Two Rochester physicians were guest speakers at a meeting of the Minnesota State Dietetic Association in Winona on November 6. Dr. Howard M. Odel discussed "The Dietary Management of Cardio-renal Disease," and Dr. John M. Berkman spoke on "Anorexia Nervosa."

* * *

Dr. A. B. Baker, professor and director of the division of neurology at the University of Minnesota Medical School, spoke on "Progress in Treatment of Infantile Paralysis" at an open forum meeting of the Duluth Chamber of Commerce on November 16. Dr. Baker illustrated his talk with photographic slides.

* * *

Dr. Edward W. Sickels has opened an office at 625 Lowry Medical Arts Building, St. Paul, for the practice of general surgery. Dr. Sickels graduated from the University of Minnesota Medical School in 1940, interned at the Harper Hospital, Detroit, Michigan, for two years, served in the Navy for four years and has been surgical resident at the Miller Hospital, St. Paul, the past two years.

Psychiatrists in Charge

L. R. Gowan, M.D. L. E. Schneider, M.D.

Physicians visiting Chicago may write in advance or call personally at the headquarters of the Chicago Medical Society, 30 North Michigan Avenue, for a copy of "This Week in Chicago Medicine," which lists the weekly clinics and medical meetings in the Cook County hospitals, medical schools and medical organizations.

* * *

A Swiss chemist, Paul Muller, has been awarded the 1948 Nobel Prize for discovering the insect-killing qualities of DDT. Searching for a drug to protect plants against insects, he discovered the properties of dichlorodiphenyl-trichoroethane which resulted in the saving of thousands of lives from insect-borne diseases during World War II.

* * *

A former fellow with the Mayo Foundation, Dr. Raymond B. Allen, now president of the University of Washington, was the commencement speaker at the fall quarter exercises December 16 at the University of Minnesota. Dr. Allen, who holds among other degrees one of doctor of medicine from the University of Minnesota Medical School, left Minnesota in 1934.

* * *

Dr. Henry F. Helmholz, Rochester pediatrician, reported in December to the International Children's Emergency Fund in New York that undernourishment was increasing among millions of European children in spite of efforts of the fund. He listed as reasons a milk shortage, crop failures and an increased child population in twelve countries receiving aid.

* * *

A former Mayo Clinic staff member, Dr. Edward D. DeLamater has been appointed associate research professor in the department of dermatology and syphilology at the University of Pennsylvania. Dr. DeLamater was formerly a consultant in mycology at the Mayo Clinic and an assistant professor of bacteriology in the Mayo Foundation.

* * *

In Osakis, Dr. Edwin E. Emerson moved into offices in his newly constructed clinic building in November. The one-story building, built of brick and glass blocks, houses a waiting room, laboratory, x-ray room, receptionist's office, emergency room and two examination rooms. Dr. Emerson has practiced in Osakis for two years.

Thirty-six persons—physicians, their wives, and employes—attended a banquet in Crookston on November 10 to observe the twenty-second anniversary of the Northwestern Clinic. A feature of the evening program was the showing of motion pictures taken by Dr. M. O. Oppegaard in California, Mexico, Central America and New York.

* * *

Dr. Victor Johnson, director of the Mayo Foundation, has been appointed to a six-man national committee to undertake a three-year study of medical education in the United States. The study, the third and largest undertaken in American medical history, is sponsored by the American Medical Association and the Association of American Medical Colleges.

* * *

An award from the Mead Johnson Company for outstanding contributions to pediatrics was given to Dr. B. M. Spock, Rochester, at a meeting of the American Academy of Pediatrics in Atlantic City in November. The award was one of two offered each year by the firm for exceptional work in pediatrics and was presented to Dr. Spock by a committee from the academy.

* * *

Six of the Minnesota physicians who attended a continuation course on the diagnosis and treatment of cancer, held at the University of Minnesota December 2, 3 and 4, were Dr. I. L. Oliver, Graceville; Dr. Douglas L. Johnson, Little Falls; Dr. A. D. Rydland and Dr. J. F. Norman, both of Crookston; Dr. Eli E. Christensen, Winona, and Dr. C. A. Saffert, New Ulm.

* * *

At the annual meeting of the staff of the Mayo Clinic on November 15, Dr. J. F. Weir was elected president of the staff, and three members who had reached the retirement age were honored. Placed on emeritus status were Dr. M. S. Henderson, Dr. W. A. Plummer and Dr. Charles Sheard. Dr. Henderson joined the clinic in 1907, Dr. Plummer in 1910, and Dr. Sheard in 1924. Other officers elected at the meeting included Dr. Della G. Drips, vice president, and Dr. E. N. Cook, secretary.

* * *

The board of directors of the Community Health Center and Clinic in Two Harbors announced during the middle of November that Dr. Joseph Bloom, formerly of New York, had arrived to join the clinic staff. A

graduate of the New York Medical College, Dr. Bloom has served as chief resident surgeon at the Flower and Fifth Avenue Hospitals. During the recent war he served for thirty-seven months with the army medical corps.

* * *

Representing the physicians of Granite Falls, Dr. Carl L. Lundell is a member of a newly organized school health council, which was formed to aid in co-ordinating various aspects of the school health program in Granite Falls. One of the first proposals made by the council was a physical examination for all seventh grade students. Other recommendations made by the council included expansion of the dental health program and instruction of pupils in good health practices.

* * *

Dr. Paul C. Bucy, professor of neurology and neurological surgery at the Illinois Neuropsychiatric institute, will deliver a lecture at the University of Minnesota January 27 at 8 p.m. He will speak in the auditorium of the Minnesota Museum of Natural History.

Dr. Bucy's topic will be "The Cerebral Control of Muscular Activity." The lecture is sponsored by the J. B. Johnston lecture in neurology and is open to all medical men.

* * *

The American Legion, at its convention held in Miami in October, 1948, went on record as opposed to compulsory national health insurance and passed a resolution to that effect. The resolution stresses the lowering of standards of health care, the enormous increase in taxes and the necessary increase in federal employes which such a step would entail. A copy of the resolution was mailed to 1,000 of the top leaders of the American Legion urging support of the local branches of the National Physicians Committee.

* * *

Until 1945 research in heart disease had little financial support. In 1945 the life insurance companies of the United States and Canada established the Life Insurance Medical Research Fund to which they have contributed $600,000 a year. This fund is financing more than fifty research organizations for the study of the cause of heart disease. During 1948 this fund began to be supplemented by funds from the American Heart Association and the U. S. Public Health Service, and it is estimated that in the future some $2,000,000 will be available for heart research alone.

* * *

Druggists have shown some concern over the threatened socialization of medicine, and two local Minneapolis drug stores have contributed to the National Physicians Committee. A recent issue of *Drug Topics* calls attention to marked increase in prescription trade and a corresponding lessening in the sale of proprietary remedies in England since medicine was socialized in that country in July. There has been some complaint on the part of English druggists over the increased work this entails and the delay in their receiving government checks.

* * *

Speaking at a meeting of the Minneapolis Community Chest and Council's health and medical care division in December, Dr. Charles E. A. Winslow, professor emeritus in public health at Yale University, said that a proposal supported by President Truman for federal health insurance was a "moderate middle-of-the-road course." Dr. Winslow, who is editor of the *American Journal of Public Health*, said he "cannot see the practical possibility of jumping in all at once" as is urged by some "extremists."

* * *

The St. Louis County board, at a meeting early in December, approved a new medical fee schedule for physicians caring for county patients. The new schedule, representing a 45 per cent increase over previous fees, was to go into effect January I. In commenting on the schedule, Dr. Mario Fischer, acting county health officer, said that the new fees were 43 per cent below fees for similar services charged by the Veterans Administration and also were slightly less than those granted under the Blue Shield program.

Six Duluth physicians discussed various phases of industrial medicine on December 1 at the opening of the twenty-fifth annual industrial safety school sponsored by the Duluth Chamber of Commerce. The following physicians appeared at sectional discussion meetings: Dr. W. N. Graves, who spoke on "Burns"; Dr. E. W. Minty, "Hand Infections"; Dr. J. C. O'Neill, "Eye Safety"; Dr. G. C. Doyle, "Industrial Dermatoses"; Dr. W. A. Klein, "Sprains and Strains"; and Dr. Henry Fisketti, "Hand Injuries."

* * *

After thirty-seven years of general practice in Freeborn, Dr. Carl R. Buturf moved to Minneapolis in November where he plans to "take it easy." A year ago Dr. Buturf decided to give up his country practice; he then spent twelve months trying to achieve his goal. He stayed in Freeborn for the extra year trying to help the residents interest another physician in taking over the practice, without success. Finally he closed his office.

In Minneapolis, Dr. Buturf has no intention of living a life of retirement. On the contrary, he plans to spend his time attending dermatology clinics at the University of Minnesota and at Twin Cities hospitals. After thirty-seven years of general practice, he might become a specialist!

It was announced in November that three new physicians had been added to the staff of the Lenont Peterson Clinic in Virginia. They are Dr. Merle Sharp, a graduate of the University of Louisville Medical School, with three years of training in obstetrics and gynecology at the University of Pennsylvania Hospitals; Dr. Robert Kurth, a graduate of Creighton University Medical School, who was in private practice in Iowa for eighteen months; and Dr. Nels Stransjord, a graduate of the University of Chicago School of Medicine, who has taken postgraduate work at the University of California. In the Virginia clinic Dr. Sharp is head of the department of obstetrics and gynecology, and Dr. Kurth is associated with him. Dr. Stransjord is associated with Dr. E. N. Peterson in surgery and industrial medicine. The staff of the Lenont Peterson Clinic now numbers eight physicians.

* * *

Members of the United States Chapter of the International College of Surgeons, meeting in St. Louis, Missouri, November 15 to 19, named Dr. Henry W. Meyerding, Rochester, president-elect of the group, to take office in 1950.

Minnesota physicians were represented on the program by Dr. Winchell McK. Craig and Dr. Claude F. Dixon, Rochester, who were among the sixty-four surgeons who presented papers at the meeting.

Dr. Walter C. Stillwell of Mankato was awarded a fellowship in the College, and Dr. Allen G. Janecky, Warroad, became a matriculate of the group.

Among Minnesota physicians attending the meeting were Dr. M. O. Oppegaard, Crookston; Dr. O. J. Hagen, Moorhead; Dr. M. J. McKenna, Grand Rapids, and Dr. Howard Vogel, New Ulm.

* * *

Dr. S. A. Slater of Worthington, medical director of Southwestern Minnesota Sanatorium, was honored with a certificate of achievement awarded by the Minnesota Public Health Association for "outstanding" contributions in tuberculosis control" at a dinner meeting at Christmas Seal headquarters October 18, 1948. The award was made in recognition of Dr. Slater's pioneer work in Mantoux testing for measuring the effectiveness of tuberculosis control which led to national acceptance. The fact that seven of the ten counties of Southwestern Minnesota have been accredited for outstanding records in tuberculosis control is credited in large part to Dr. Slater's efforts. He is a past president of the Minnesota Public Health Association and of the Mississippi Valley Conference on Tuberculosis and has been representative director of the National Tuberculosis Association since 1930.

* * *

Dr. and Mrs. Henry W. Meyerding of Rochester returned in November from an extended visit to Europe. During their stay, Dr. Meyerding, as president of the organization, attended the Fourth Congress of the International Society of Orthopaedic Surgery and Traumatology, in Amsterdam last summer. He also gave the opening address at the Czechoslovak Society of Orthopaedic Surgery and Traumatology in Prague on September 23, and was made an honorary member of the society. The Netherlands Orthopaedic Association and the French Surgical Society also made him an honorary member. While in Paris, he attended the Congress of the French Surgical Society and the French Orthopaedic Society. Dr. Meyerding has been named president-elect of the United States Chapter of the International College of Surgeons and will take office for two years beginning in 1950.

* * *

The annual Detroit Orthopaedic Lecture, under the auspices of the Wayne County Medical Society, was delivered on December 6 by Dr. Vernon L. Hart of Minneapolis. Dr. Hart presented a copy on "Congenital Dislocation of the Hip: Recognition and Treatment during Infancy before Weight Bearing." He also showed a colored motion picture on the same subject.

University of Minnesota physicians contributed a major portion of the program at a gastric cancer conference sponsored by the National Cancer Institute in San Francisco December 13 and 14.

Minnesota speakers at the meeting included Dr. Leo G. Rigler, professor and chief of radiology and physical therapy; Dr. David State, assistant professor of surgery and director of the University's Cancer Detection Center; Dr. Charles F. Code, professor of physiology at the Mayo Foundation; Dr. Robert Hebbel, associate professor of pathology; Dr. Stanley R. Friesen, instructor in surgery, and Dr. George E. Moore, clinical instructor in surgery and a fellow of the National Institute of Public Health.

ANNOUNCES CONTINUOUS COURSES

SURGERY—Intensive Course in Surgical Technique, two weeks, starting January 24, February 21.
Surgical Technique, Surgical Anatomy and Clinical Surgery, four weeks, starting February 7, March 7.
Surgical Anatomy and Clinical Surgery, two weeks, starting February 21, March 21.
Surgery of Colon and Rectum, one week, starting March 7, April 11.
Surgical Pathology every two weeks.

GYNECOLOGY—Intensive Course, two weeks, starting February 21, March 21.
Vaginal Approach to Pelvic Surgery, one week, starting February 14.

OBSTETRICS—Intensive Course, two weeks, starting March 7.

MEDICINE—Intensive Course, two weeks, starting April 4.
Personal Course in Gastroscopy, two weeks, starting March 7.

PEDIATRICS—Intensive Course, four weeks, starting April 4.

DERMATOLOGY—Formal Course, two weeks, starting April 18.
Clinical Course every two weeks.

CYSTOSCOPY—Ten-Day Practical Course every two weeks.

ROENTGENOLOGY—Lecture and Diagnostic Course, two weeks, starting the first Monday of every month.
Clinical Course starting third Monday of every month.

General, Intensive and Special Courses in all Branches of Medicine, Surgery and the Specialties

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 S. Honore St., Chicago 12, Ill.

Comments by a British subject in regard to Great Britain's expanded health service were recently forwarded to MINNESOTA MEDICINE by Dr. N. O. Pearce, acting director of the division of cancer control, Minnesota Department of Health. Excerpts from a letter, which Dr. Pearce received from England in December, follow:

"I noticed a suggestion that there is being prepared for you a health and insurance scheme to cover you from cradle to coffin. If it is offered to you, I have a feeling you will find the idea very indigestible.

"We have now had five months of the enlarged health service, and as regards the professions, the situation seems to be like this:

"Demand for hospital accommodation has increased tremendously.

"The doctors, in what is normally a healthy period, have been swamped with work, and, in great numbers of cases, are finding severe cuts in their earnings as well as some difficulty in gathering their pay.

"Private practice has almost faded out; this was hardly expected. Dentists and opticians have long waiting lists; already vast numbers of dentures and spectacles have been supplied without cost (except, of course, that women up to sixty and men up to sixty-five have to maintain their weekly contribution). The earnings of the dentists and opticians have been beyond their dreams. We pharmacists have seen dispensing doubled, probably much more than doubled, but remuneration for this is very much more modest, and many are feeling acute difficulty in the heavy outlay in drugs and expensive 'specials' and the long delay between the costing and payment of same. The thought of any sort of epidemic frightens us."

* * *

The Minneapolis War Memorial Blood Bank at 1914 LaSalle Avenue (the former home of Charles B. Rogers) was dedicated on Armistice Day, November 11, 1948, at which time the remodeled building and equipment were open for public inspection.

The original cost of the bank was raised by the Junior Chamber of Commerce of Minneapolis through subscriptions. The director is Dr. Rudolph Koucky, and the Board of Directors is composed of a third doctors, a third hospital administrators and a third civic minded citizens.

For obtaining blood donations, donor clubs have been organized in various industrial plants, church clubs and the like, a fifth of the members of each group agreeing to make a donation of blood each year which entitles the donor and his family free blood in case of need.

The Minneapolis Blood Bank supplies the hospitals and surrounding territory at a nominal charge of $6.00 per unit to cover laboratory work.

The St. Paul Regional Blood Center, operated by the American Red Cross, began operation December 15, 1948, at 91 East Kellogg Boulevard. Dr. E. V. Goltz is in charge.

The St. Paul Center will supply hospitals in Ramsey, Washington, Dakota, Chisago, Isanti, Freeborn, Mower, Winona, Steele, Rice, Blue Earth and Goodhue Counties in Minnesota and Polk, St. Croix, Pierce, Dunn, Chippewa, Eau Claire, Pepin and Barron Counties in Wisconsin.

The generosity of the public in the territory supplied will be relied upon for donors, mobile units to be used for collecting donations from the surrounding territory.

HOSPITAL NEWS

The physicians' lounge in the Montevideo Hospital, after being in use since 1900, is to be replaced with a new one, it was announced in late November. A check for $1,000 has been presented to the hospital for that purpose by Mrs. L. R. Lima, widow of the late Dr. L. R. Lima of Montevideo.

* * *

In November, Dr. C. A. Traeger, chief of the medical staff of St. Lucas Deaconess Hospital in Faribault, announced that five physicians had been elevated from associate to active staff membership. The five physicians are Dr. D. W. Francis, Morristown; Dr. F. J. Lexa, Lonsdale; Dr. F. C. Meyer, Kenyon; Dr. R. R. Moses, Kenyon, and Dr. C. A. Rohrer, Waterville.

* * *

The Willmar State Hospital provided conducted tours for the public during the first week of December as part of the observation of Mental Health Week. The tours were arranged to give the public a better idea of the problems and procedures in a mental hospital and to show how the use of restraints could be reduced if sufficient hospital personnel were available. At the time of the tours an experimental anti-restraint program had been started at the hospital, but due to lack of personnel the

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

PSYCHIATRISTS IN CHARGE
Dr. Hewitt B. Hannah
Dr. Joel C. Hultkrans

2527 2nd Ave., S., Minneapolis, Phone AT. 7369

non-restraint techniques could be used in only three of the hospital's cottages. Where the experimental techniques were used, however, it was found that the number of restraints could be greatly reduced. The program was under the direction of Dr. Stanley B. Lindley, hospital superintendent.

* * *

Contracts totaling $849,554 for the construction of the Variety Club Heart Hospital at the University of Minnesota were awarded December 17, 1948, to three Twin Cities contractors, and work on the project started shortly after Christmas.

Bids for the new eighty-bed hospital to be erected on the Mississippi River bank adjacent to University Hospitals were opened November 24, and held open pending action on a University application for $325,334 of federal funds under the Hill-Burton Hospital construction act.

Upon notification from the United States Public Health Service of approval of a grant of $310,271 for construction of the hospital building and an additional grant of $15,063 for the purchase of equipment, University officials awarded contracts to the low bidders.

Successful bidder for the general contract is the firm of Naugle-Leck, Inc., of Minneapolis with a net figure of $573, 575. The plumbing, heating and ventilating work was awarded to Reuben L. Anderson, Inc., St. Paul, on a bid of $214,920, while the Batzli Electric Company of Minneapolis took the electrical contract with a low bid of $61,059. The contracts call for completion of the project within a period of 548 days.

Completed, the new hospital, with equipment, is expected to cost $987,285. Funds which will pay the structure will come from the following sources: Variety Club of the Northwest, $464,000 ($304,000 of which has been raised and an additional $160,000 pledged); grant of federal funds under the Hill-Burton Act, $325,334; University funds now on hand from several sources, $97,951; and a bank loan of $100,000 to be repaid over a ten-year period.

* * *

Despite spiraling costs of operations and a severe shortage of staff, University of Minnesota Hospitals cared for more patients during the year ending last June 30 than in any previous year, according to the annual report of Ray M. Amberg, hospitals director.

During the year, 9,752 patients were admitted to the hospitals for treatment as compared with 9,532 admitted during the previous year and 9,220 during 1945-46. The hospitalization period averaged 14.1 days, while the average for the year before was 15.2 days and for 1945-46, 15.4 days.

Surgical operations performed in University Hospitals totaled 7,603, an increase of 865 over the previous twelve months and 1,908 over the year 1945-46.

Visits to the hospitals' out-patient department during the period totaled 90,566. Compared with the 80,611 visits recorded in 1946-47 and the 74,110 calls made by patients during 1945-46 for diagnosis and treatment, this figure illustrates the increasingly heavy load being borne by this division of University Hospitals.

Startling increases in the costs of operating the hospitals were disclosed by Amberg in his annual report. In-patient department costs soared from $9.49 per patient per day in 1945-46 to $12.02 in 1946-47 and to $16.31 in 1947-48, a boost of $6.82 in two years—$4.29 in the last year alone. The cost per patient visit in the out-patient department averaged $3.72 during the last year or 58 cents above the $3.14 cost during 1946-47 and 87 cents over the 1945-46 visit cost of $2.85.—University of Minnesota News Service, October 8, 1948.

BLUE SHIELD NEWS

Applications received for Blue Shield to November 30, 1948		116,466
Blue Shield cases paid from November 1 to November 30, 1948		886
	Total....1948	3,459
Amount paid on Blue Shield cases from November 1 to November 30, 1948		$ 33,139.38
	Total....1948	$128,814.18

As each supplemental list of licensed and registered doctors of medicine is released by the Minnesota State Board of Medical Examiners, Minnesota Medical Service, Inc. (Blue Shield) receives a copy. The physicians on this list are usually non-participating, unless they have previously contacted the Blue Shield office relative to becoming participating.

The last supplemental list received in the Blue Shield office contained the names of about seventy physicians residing in Minnesota who were not participating in the

Blue Shield plan. In September, 1948, letters and descriptive literature explaining the plan were sent to these physicians, but to date only a very small percentage of them have returned their signed applications. Perhaps many of these gentlemen are not in private practice, or do not reside in Minnesota, or cannot become participating doctors for one reason or another, we do not know. However, it is felt that many of these doctors could and should participate. Undoubtedly, in some cases this Blue Shield material has been misplaced or perhaps slipped the physician's mind and is only called to his attention on the day he renders service to a Blue Shield subscriber.

With the increasing number of persons covered by Blue Shield in Minnesota, more and more physicians are rendering service to Blue Shield patients. For a number of reasons, the newly licensed and registered doctors should give some consideration to becoming Blue Shield participating doctors. In the first place, Blue Shield reduces the collection problem for the doctor, for all allowances on Blue Shield cases are made directly to the physician within ten days after the report form is received in the Blue Shield office. Secondly, according to the Blue Shield subscriber's contract, an allowance of only 75 per cent of the maximum amount allowable would be paid to a non-participating doctor, in which case the Blue Shield subscriber patient is penalized and the doctor can also be hurt in that it is his problem to collect any balance due.

If the doctors in a state can show wholehearted support and co-operation with a prepaid medical care plan, such as Blue Shield, they have a powerful weapon with which to combat government medicine, and will not have to think of the future as one Minnesota doctor recently expressed it in a letter to the Blue Shield, "To have to move to the Fiji Islands and practice for cocoanuts and rum."

May we also express the opinion that other non-participating doctors throughout the state give the above some thought. Any additional information or application cards for enrollment may be obtained from the Blue Shield office.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

ANATOMICAL CHARTS TO BE PUBLISHED IN BOOK FORM

Soon to be issued in book form are the Ciba illustrations of anatomy and pathology which were prepared by Frank H. Netter, M.D. These full color drawings have been distributed to physicians for the last several years in portfolio form by Ciba Pharmaceutical Products, Inc., Summit, N. J.

These anatomical charts have been widely acclaimed in the medical profession. In many medical schools they are used as teaching aids and physicians have found them valuable in office instruction of patients.

While portfolios of new drawings will be issued from time to time, the new book will bring together those that were distributed up to January 1, 1948.

The book will measure 9½ x 12½ inches and contain 224 pages, showing 191 of these anatomical charts printed in full color. It will be sold by Ciba at a price to cover only the actual printing and binding costs.

The subjects covered in the book will be as follows:

Subject	*Number Full-Color Plates*
The Lungs and Chest	36
Injuries to the Chest	12
The Esophagus	12
The Stomach	19
The Duodenum	12
The Small Intestine	20
The Colon	20
Injuries of the Abdomen	10
The Testicle	14
The Prostate	5
The Male Breast	2
The Female Breast	18
The Heart and Aorta	11

The illustrations will be printed on 80-pound gloss enamel paper and the book will be bound in boards with blue buckram covering and the title stamped in genuine gold on the front and spine.

TREATMENT BY DIET, by Clifford J. Barborka, B.S., M.S., M.D., D.Sc., F.A.C.P.; Assistant Professor of Medicine, Northwestern University Medical School, Chicago; Attending Physician, Passavant Memorial Hospital; Consultant in Gastro-enterology and Gastroscopy, Diagnostic Center, Hines Veterans Hospital; Formerly Consulting Physician, The Mayo Clinic. 5th ed. 784 pages. Illus. Philadelphia, London, Montreal; J. B. Lippincott Co., 1948. Price $10.00.

In the mysterious field of the medical uses of diet, Dr. Barborka has written a clear, though somewhat bulky, exposition of the medical uses of food. His book is divided, logically, into a discussion of normal diet and diet in pathological states; then further divided into those pathological states in which diet is of paramount importance, such as diabetes mellitus, Addison's disease, and so on, and those in which diet is of variable importance, such as heart disease and various infections.

Though the author includes many diseases in the last section in which diet is of trivial importance, he does maintain a reasonable sense of the relative importance of diet. His point of view is realistic; he is specific and direct. His discussion of theory is reduced to a minimum. The typical diets and tables are varied and numerous. In summary, Treatment by Diet is of value to anyone, from the dietitian to the general practitioner, who must prescribe diets. JOHN B. MCADAMS, M.D.

Successful rehabilitation requires a comprehensive and effective sanatorium program and close co-operation between the sanatorium and the community. All of the community services must be integrated to serve the patient and family during all the phases of treatment, from the time of diagnosis until the individual is fully adjusted. Under these conditions patients will accept sanatorium care, remain till their tuberculosis is arrested and follow through with necessary rehabilitation plans. —I. D. BOBROWITZ, M.D.

★★ POSITIONS AVAILABLE ★★

- Young physician with active practice near Twin Cities wants young, sincere general practitioner as associate. Partnership if congenial.
- Board man in surgery has opening for physician who has completed residency requirements toward certification in surgery.
- Physician-in-Charge wanted by blood center in West. Some training in pathology desirable but not essential. Minimum starting salary, $7,200.
- Two general practitioners for industrial positions. One part-time, Twin Cities. The other full-time, Southern Minnesota.
- A number of openings in various localities for GP's and board men in most specialties.

Glenwood Hills Hospitals

SCHOOL OF PSYCHIATRIC NURSING

- The professional standing of the 18 members of our teaching staff is well known to you. Qualified instructors of highest repute.
- Our modern methods in modern patient care, achieved in a sensible one-year course have received unstinted praise.
- The record of our graduates is outstanding and they are preferred by doctors and clinics.

Ask any nurse who has enjoyed the benefits of this specialized, time-conserving course what she thinks of having chosen this as her professional career. You will find in her a competency, an adequacy and an economic security that is rare.

IF YOU, as a physician care to do something to relieve the nursing shortage now apparent on every hand, with hospitals closing off floors because handicapped for lack of help, act now. In the psychiatric field there is a crying need for nurses. Nominate some promising girl, 17 years of age or older, with high school background.

- *We will send one of our booklets to you and another one to her.*
- *She will thank you and you will be gratified; our most capable graduates are those doctor-recommended.*
- *We will sincerely appreciate your co-operation.*

June class is now being made up

Tuition is Free . .

with a small fee for matriculation.

It Can Happen Here

Example of severe rickets in a sunny clime.

LEST WE FORGET—we who are of the vitamin D era—severe rickets is not yet eradicated, and moderate and mild rickets are still prevalent. Here is a white child, supposedly well fed, if judged by weight alone, a farm child apparently living out of doors a good deal. This boy was reared in a state having a latitude between 37° and 42°, where the average amount of fall and winter sunshine is *equal to that in the major portion of the United States*. And yet such stigmata of rickets as *genu varum* and the quadratic head are plain evidence that rickets does occur under these conditions.

How much more likely, then, that rickets will develop among city-bred children who live under a smokepall for a large part of each year. True, vitamin D is more or less routinely prescribed nowadays for infants. But is the antiricketic routinely administered in the home? Does the child refuse it? Is it given in some unstandardized form, purchased from a false sense of economy because the physician did not specify the kind?

A uniformly potent source of vitamin D such as Oleum Percomorphum, administered regularly in proper dosage, can do more than protect against the gross visible deformities of rickets. It may prevent hidden but nonetheless serious malformations of the chest and the pelvis and will aid in promoting good dentition. Because the dosage is measured in *drops*, Oleum Percomorphum is well taken and well tolerated by infants and growing children.

OLEUM PERCOMORPHUM WITH OTHER FISH-LIVER OILS AND VIOSTEROL

Potency, 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10 cc. and 50 cc. bottles; and as capsules in bottles containing 50 and 250.

The first estrogen

isolated in pure crystalline form—and still the standard of reference for measuring estrogen activity—THEELIN has been a stand-by for over two decades. Its effectiveness in controlling symptoms and signs of the menopause and other estrogen-deficient states is attested to by hundreds of published reports. The notable freedom from undesirable side effects of this naturally occurring estrogenic hormone has long been familiar to physicians everywhere.

THEELIN's dose-for-dose uniformity is assured by chemical determination of identity and purity, and standardization by weight. The variety of clinically convenient dosage forms permits individualized treatment schedules.

THEELIN AQUEOUS SUSPENSION 1-cc. ampoules of 1 mg. (10,000 I.U.), 2 mg. (20,000 I.U.), and 5 mg. (50,000 I.U.).

THEELIN IN OIL 1-cc. ampoules of 0.1 mg. (1000 I.U.), 0.2 mg. (2000 I.U.), 0.5 mg. (5000 I.U.) and 1 mg. (10,000 I.U.).

THEELIN STERI-VIALS® IN OIL, vials of 10 cc., 1 mg. (10,000 I.U.) per cc.

nly

even after 40,

a woman does creative work...

The urge to do creative or constructive work is often rekindled in the woman relieved of menopausal symptoms. Restraints placed on her talents by the nervousness, hot flushes and other manifestations of the climacteric may vanish entirely following the use of ***"Premarin."***

In addition, there is a "plus" in ***"Premarin"*** *therapy...the gratifying "sense of well-being" so frequently reported by the patient. Oral activity, comparative freedom from side-effects and flexibility of dosage are other advantages associated with this naturally-occurring, conjugated estrogen.* ***"Premarin"*** *is supplied in tablets of four different potencies and in liquid form.*

Ayerst

While sodium estrone sulfate is the principal estrogen in ***"Premarin,"*** *other equine estrogens...estrodiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.*

"PREMARIN"®

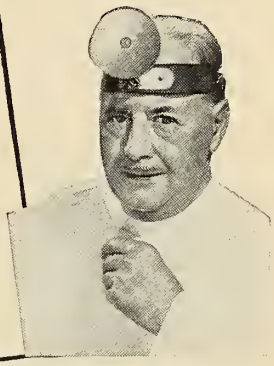
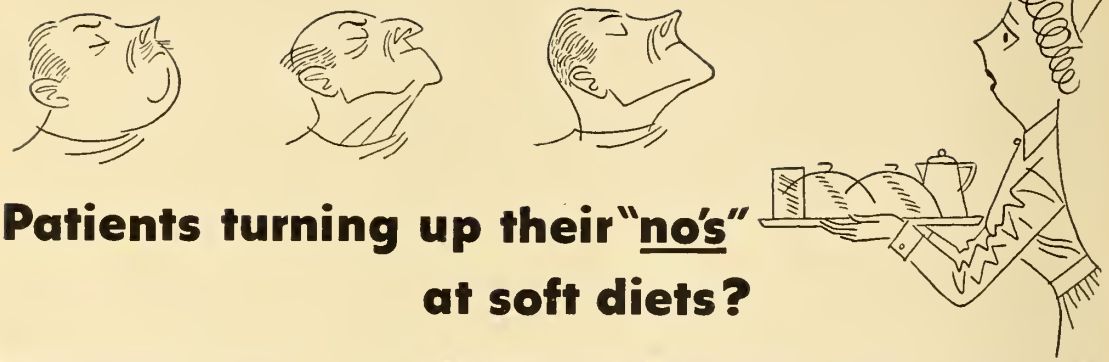
Prove
CAMEL MILDNESS
for Yourself!
CAMEL
TURKISH & DOMESTIC BLEND CIGARETTES
CHOICE QUALITY
Money-Back Guarantee!
Test Camel Mildness for yourself in your own "T-Zone"—T for taste, T for throat. If, at any time, you are not convinced that Camels are the mildest cigarette you ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. (Signed) R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina.

In a recent coast to coast test of hundreds of people who smoked only Camels for 30 days, throat specialists, after weekly examinations, reported:

"Not one single case of throat irritation due to smoking CAMELS!"



Hundreds of men and women were included in this coast to coast test. These men and women smoked Camels—and only Camels—for 30 consecutive days. They smoked on the average of one to two packages a day. Each week noted throat specialists examined the throats of these Camel smokers—a total of 2470 careful examinations. In every report, the findings of these throat specialists were the same—"not one single case of throat irritation due to smoking Camels."



According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel.

Patients turning up their "no's" at soft diets?

Try tasty, protein-rich Swift's Strained Meats!

A palatable, natural source of complete, high-quality proteins

It's not surprising that soft-diet patients develop appetite-apathy. The things they have to eat!

To help overcome this anorexia many doctors now recommend Swift's Strained Meats. Delicious, *real* meat that patients on soft, smooth diets can eat and *enjoy*. Swift's Strained Meats provide an excellent base for high-protein, low-residue diet. Rich in iron, they're chemically and physically non-irritating. They make available *simultaneously all* essential amino acids for optimum protein synthesis.

Swift's Strained Meats are tasty enough to tempt tired appetites. They supply goodly amounts of B vitamin to help stimulate patients' natural appetite for other foods. Swift's Strained Meats are 100% meat—a variety of six kinds: beef, lamb, pork, veal, liver, heart. Originally prepared for infant feeding, they're exceptionally fine in texture—may easily be used in tube feeding. Convenient—ready to heat and serve.

6 varieties:
Beef, lamb, pork, veal, liver, heart

For patients who can take foods of less fine consistency—Swift's Diced Meats offer tender morsels of nutritious meats with tempting flavors patients appreciate.

The makers of Swift's Strained Meats invite you to send for your copy of "The Importance of Protein Foods in Health and Disease"—a physicians' handbook of protein feeding, written by a doctor. Send to:

Old Age NEED NOT MEAN *Chronic Illness*

Clinical studies[1,2,3] demonstrate that the results of inadequate dietaries are insidiously cumulative and may not become evident for many years. Many of the afflictions of old age are now attributed to lifelong faulty dietaries and no longer need be the inevitable accompaniment of advanced years.

In advanced age the wisdom of dietaries high in vitamins, minerals, and protein, low in fat, and moderate in carbohydrate, is pointedly emphasized in reported clinical studies. Liberal amounts of vitamin B complex and of calcium, in particular, are important for increasing the appetite and for supporting the calcium integrity of the skeletal structure.

Ovaltine in milk, a delicious *multiple* dietary supplement, is highly useful in the management of aged patients. Its multiple vitamins, its important minerals, and its biologically complete protein are the very nutrients required for effecting full adequacy of even seriously faulty diets. The refreshing tastefulness and easy digestibility are welcomed by the aged.

The rich dietary contribution made by three daily glassfuls of Ovaltine in milk, is outlined in detail in the table.

WHEN HE'S TEMPTED BY FORBIDDEN FOODS . . .

What's a man to do? He's tired of dieting. The vision of new health and a better figure faded with the first 10 pounds . . . and now all he can see wherever he goes is food, food, tempting food . . .

● One 2.5 mg. tablet of DESOXYN Hydrochloride, an hour before breakfast and lunch, can provide meal-to-meal aid in curbing the appetite. It also imparts a desire for greater activity and decreases the feeling of fatigue. A third tablet may be taken in midafternoon if necessary, and if it does not cause insomnia. ● Weight for weight, DESOXYN is more potent than other sympathomimetic amines, so that *smaller doses* may be used. Many investigators who have used DESOXYN extensively claim that its action is *faster* and *more prolonged* with relatively *few side-effects*. With the correct dosage, little or no pressor effect has been observed.

● As an adjunct to the treatment of obesity, as relief for the depression of convalescence, as a safe, effective stimulant for the central nervous system, remember DESOXYN Hydrochloride. For the complete story on indications and dosages, write to ABBOTT LABORATORIES, North Chicago, Illinois.

Facts About Conception Control

Clinicians generally favor the use of an occlusive device supplemented by a sperm-immobilizing agent for optimum protection. However, authoritative studies have established that a high degree of protection is afforded by use of a jelly alone—provided that the jelly has rapid spermatocidal action together with adhesive and cohesive properties sufficient to provide a dependable barrier.

When dependence must be placed on the "jelly alone" method, there is no better product available than "RAMSES"* Vaginal Jelly† because:

1. It provides rapid spermatocidal action.

2. It possesses dependable adhesive and cohesive properties—will not melt or run at body temperatures.

3. Direct-color photographs show that it will occlude the cervix for ten hours.

"RAMSES" Vaginal Jelly is available in regular and large-size tubes through all pharmacies.

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

CRYSTALS OF
FOLIC ACID

Nutritional Research

During the past several years, Lederle has made a very substantial investment in time and money for the investigation of nutritional deficiency states. The vast majority of such investigations lead down dead-end streets, but occasionally—and most fortunately for mankind—a brilliant result is achieved. One of the fields in which these efforts have proven, and are proving, successful is the field of nutritional macrocytic anemias. The first step in the conquest of this field was the perfection of a practicable intramuscular liver extract by Lederle several decades ago. More recently, the Lederle-Cyanamid research team isolated and synthesized folic acid, which has been proven specific for the macrocytic anemias of sprue, infancy and childhood, pregnancy, gastrointestinal dysfunction, and pellagra. We are close to a solution of many other similar nutritional problems. FOLVITE* Folic Acid *Lederle*, in various forms, is available for prescription use.

CHECK LIST

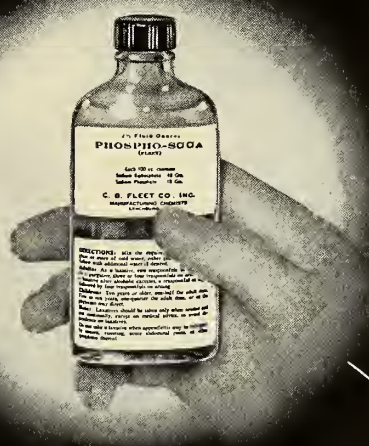
for choice of a laxative

Phospho-Soda (FLEET)* TYPE OF ACTION

- ✓ Prompt action
- ✓ Thorough action
- ✓ Gentle action

•

SIDE EFFECTS



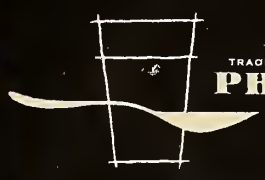
- ✓ Free from Mucosal Irritation
- ✓ Absence of Constipation Rebound
- ✓ No Development of Tolerance
- ✓ Safe from Excessive Dehydration
- ✓ No Disturbance of Absorption of Nutritive Elements
- ✓ Causes no Pelvic Congestion
- ✓ No Patient Discomfort
- ✓ Nonhabituating
- ✓ Free from Cumulative Effects

•

ADMINISTRATION

- ✓ Flexible Dosage
- ✓ Uniform Potency
- ✓ Pleasant Taste

Judicious Laxation



through controlled action

Phospho-Soda (Fleet)*, over the years, has won discriminating preference by thousands of physicians . . . because of its controlled action— its freedom from undesirable side effect—and its ease of administration. Your prescription of Phospho-Soda (Fleet)* assures effective (and safe) results. Liberal samples on request.

For surface infections . . .

Although burned tissues supply an excellent medium for bacterial growth, infection may be minimized by the prompt, topical application of an efficient antibacterial agent. For this purpose, fine-mesh gauze strips impregnated with Furacin Soluble Dressing may be used. The effectiveness of Furacin in combatting mixed infections of burns without delay of healing has been well demonstrated.* Furacin N.N.R., brand of nitrofurazone, is available as Furacin Soluble Dressing and as Furacin Solution, both containing 0.2 per cent Furacin.® These preparations are indicated for topical application *in the prophylaxis and treatment of infections of* wounds, second and third degree burns, cutaneous ulcers, pyodermas and skin grafts. *Literature on request.*

Volume 32 **February, 1949** **No. 2**

BACKGROUND OF PROBLEM ARISING THROUGH ATTEMPT TO LICENSE FOREIGN MEDICAL GRADUATES

PRIOR to 1937 the Minnesota State Board of Medical Examiners had admitted to its examinations a number of so-called foreign medical graduates. In its attempt to license only those foreign medical graduates whose medical education and moral qualifications were on a par with the graduates of the medical school of the University of Minnesota, it became apparent to the Medical Board that the problem was becoming more difficult of solution for the following reasons:

1. No agency existed for the grading and classification of medical schools outside of the United States and Canada, thus making it practically impossible for the Medical Board to determine whether or not the medical school was one to be approved by the Board.

2. With the approach of war in Europe in 1939, it was no longer possible for the Medical Board to satisfactorily determine the applicant's qualifications as to good moral character. This includes whether or not the applicant was ever convicted of a felony or an offense involving moral turpitude; of whether or not the applicant was addicted or had ever used any habit forming drugs, such as the various derivatives of opium; whether or not the applicant had ever had a previous issued medical license revoked, et cetera.

3. It was also discovered by the Medical Board that a considerable number of American medical students who had failed in their medical course in medical schools in this country, had gone to Europe to continue their medical education, and, in certain instances, had been permitted to enter a European medical school as advanced medical students without any requirement that they take further training in the medical subjects in which they had failed.

4. It was also discovered that it was becoming increasingly difficult, if not impossible, for an American citizen who was a graduate of a medical school such as the University of Minnesota, or any other Class A medical school in this country, to become licensed in any of the European countries without the surrender of his American citizenship.

The Minnesota State Board of Medical Examiners, believing that its first duty is to the public generally, and that the maintenance of high standards in medical education and licensure are a protection to the people of this State, adopted, on November 12, 1937, the following resolution. It was not intended that the resolution was to be a fixed and permanent rule of the Board, but rather that it was subject to amendment if and when the requirements could be relaxed without sacrificing any protection to the people of the State.

RESOLUTION

In Reference to Foreign Medical Graduates

Adopted by Minnesota State Board of Medical Examiners on November 12, 1937.

WHEREAS, following a study made by the Board it appears that facilities are available for the grading of medical schools in the United States of America and in the Dominion of Canada, and it

FURTHER, appearing that no discrimination is made by the various Canadian Provinces against holders of

Article prepared by the Minnesota State Board of Medical Examiners.

Minnesota licenses who are citizens of the United States, and it

FURTHER, appearing that at the present time there are no suitable or practical facilities available to this Board for the grading and classification of medical schools outside of the United States of America and the Dominion of Canada and that citizens of the United States holding Minnesota licenses are not eligible for licensure other than as outlined above, and it appearing that there is no practical way of determining the medical and other qualifications of the so-called foreign applicants, it is found necessary that the following rules and regulations be adopted as to eligibility for examination.

1. A citizen of the United States of America who is a graduate of a Class A Medical School in the United States of America recognized by the Board, is eligible to examination upon furnishing the proof of good moral character, the necessary attendance in school, graduation and degree as required by the laws of this State and the rules and regulations of this Board.

2. A citizen of Canada who is a graduate of a Class A Medical School in the United States of America or the Dominion of Canada, recognized by the Board, is eligible to examination upon furnishing the proof of good moral character, the necessary attendance in school, graduation and degree as required by the laws of this State and the rules and regulations of this Board.

3. All other applicants must

(a) Be citizens of the United States;
(b) Present proof of attendance in a Class A Medical School recognized by the Board, and proof of graduation and degree, as required by the laws of this State and the Rules and Regulations of this Board;
(c) All credentials from foreign schools and institutions must be translated into the English language over the seal and signature of the American Consul in the country wherein such documents were issued;
(d) Present evidence satisfactory to the Board of good moral character;
(e) Present evidence satisfactory to the Board that applicant holds a valid license to practice medicine and surgery in the country where his medical education and degree were obtained.
(f) Present evidence satisfactory to the Board that a medical licentiate of the State of Minnesota is granted reciprocal privileges in the country in which applicant received his medical education, degree and license.
(g) Resolved that all former rules of the Board inconsistent with these resolutions be hereby rescinded.

RESOLVED, that the foregoing be effective from date of November 12, 1937.

* * *

Adopted by the following vote: Ayes—7; Nays—0.

Laws of the State of Minnesota in Reference to the Licensure of Physicians and Surgeons

The laws of the State of Minnesota provide for a state board of medical examiners.

"which shall consist of seven qualified resident physicians appointed by the Governor in the manner hereinafter prescribed."

The law further provides that:

"The board shall have authority to prescribe such rules and regulations relative to the examination of applicants for license to practice medicine, surgery, and obstetrics as may be found necessary."

Sec. 147.01 Minnesota Statutes for 1945.

With respect to the qualifications of the applicant for licensure, the law provides:

"A person not already authorized to practice medicine in the state and desiring so to do shall apply to the secretary of the state board of medical examiners for examination and pay a fee of $20.00 for the use of the board, which in no case shall be refunded. At a time appointed, or at the next regular examination, he shall prove that he is of good moral character, that he has completed four entire sessions of not less than 36 weeks each at a medical school recognized by the board, and received the degree of M.D. or M.B. He shall be examined in surgery, medicine, obstetrics, eye, ear, nose, and throat, and such other branches as the board shall deem advisable. After such examination, the board, if five members thereof consent, shall grant him a license to practice medicine. The examination shall be both scientific and practical and thoroughly test the fitness of the candidate. The board may refuse to grant a license to, or may suspend or revoke the license of, any person guilty of immoral, dishonorable, or unprofessional conduct, but subject to the right of the applicant or licentiate to appeal to the district court in the proper county on the questions of law and fact."

Sec. 147.02 Minnesota Statutes for 1945.

With respect to the licensing of physicians who hold a medical license in another state, or who are diplomates of the National Board of Medical Examiners, the laws of Minnesota provide as follows:

"The state board of medical examiners, either with or without examination, may grant a license to any physician licensed to practice by a similar board of another state or the national board of medical examiners who holds a certificate of registration showing that an examination has been made by the proper board, in which an average grade of not less than 75 per cent was awarded to the holder thereof, the applicant and holder of such certificate having been at the time of the examination the legal possessor of a diploma from a medical college in good standing in this state, which diploma may be accepted in lieu of an examination as evidence of qualification. In case the scope of the examination was less than that prescribed by this state, the applicant may be required to submit to an examination in such subjects as have not been covered. The fee for such examination shall be $75.00.

"A certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for registration in this state; provided, the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in this state and that the date thereof was prior to the legal requirements of the examination test in this state."

Sec. 147.03 Minnesota Statutes for 1945.

The laws of the State of Minnesota, also provide that unless like reciprocity is granted a graduate in medicine of the University of Minnesota, and the holder of a Minnesota medical license, that reciprocity shall not be extended by this State; the law reading as follows:

"If by the laws of any state or the rulings or decisions of the appropriate officers or boards thereof, any burden, obligation, requirement, disqualification, or disability is put upon physicians registered in this state or

holding diplomas from medical colleges in this state which are in good standing therein, affecting the right of these physicians to be registered or admitted to practice in that state, then the same or like burdens, obligations, requirements, disqualification, or disability shall be put upon the registration in this state of physicians registered in that state or holding diplomas from medical colleges situated therein."

Sec. 147.04, Minnesota Statutes for 1945.

Licensure Experience of the Minnesota State Board of Medical Examiners

From 1928 to 1948, inclusive, the Minnesota State Board of Medical Examiners has licensed 5,063 physicians as follows:

By examination	4,194
By reciprocity with other states	562
National Board of Medical Examiners	307
Total	5,063

The records of the Medical Board disclose that within the past 21 years over 99 per cent of those taking the examination have passed and have been licensed.

Commencing with 1928, physicians have been required to register annually with the State Board of Medical Examiners. In 1928 Minnesota had 3,279 registered physicians of whom 3,051 registered from within the borders of Minnesota. In 1948 Minnesota had 5,737 registered physicians of whom 4,108 were registered from within the borders of the State, a net gain of 1,057 physicians within the State. Minnesota has a ratio of one physician to about 700 persons.

Requirement of Citizenship for Physicians and other Professional Groups

Lawyers

Rule 2 of the Supreme Court of Minnesota in reference to the admission of lawyers to practice law in the State of Minnesota, provides that the applicant shall be twenty-one years of age, of good moral character, a citizen of the United States of America and a resident of the State of Minnesota.

Dentists

"Every applicant for a license to practice dentistry, whether by examination or reciprocity, shall produce evidence satisfactory to the board that he is a citizen of the United Sates."

Sec. 150.04 Minnesota Statutes 1945.

Pharmacists

"To be entitled to examination by the board as a pharmacist the applicant shall be a citizen of the United States, of good moral character, at least 21 years of age, and shall be a graduate of the college of pharmacy of the University of Minnesota or of a college or school of pharmacy in good standing of which the board shall be the judge and shall have at least one year of practical experience in pharmacy."

Sec. 151.10 Minnesota Statutes 1945.

Physicians and Surgeons

The Minnesota State Board of Medical Examiners has been of the opinion for a number of years that every person who practices medicine in Minnesota, should be a citizen. The duties of a physician are many and varied; he is not only called upon to take care of his patients, whether it be in the office, hospital or home, but he is also called upon to appear in Court as a witness for his patient, as an expert witness designated by the Court in criminal cases, sanity hearings, etc. Because of the close personal relationship occupied by a physician with his patient and with matters pertaining to the Courts and Government, the Medical Board was of the opinion that these facts alone justified the requirement of citizenship. The Medical Board also felt that it was manifestly unfair to have doctors of American citizenship discriminated against in European countries, and at the same time, license doctors from those countries practicing such discrimination. During World War II the United States Government declined to grant commissions in the Medical Corps of the Army or Navy to doctors who were not citizens.

The Medical Board made an exception in reference to Canadian doctors for three reasons:

1. Canadian medical schools are inspected and evaluated the same as American medical schools.
2. It is a relatively simple matter to check up on the background of a Canadian medical applicant.
3. None of the Canadian Provinces require an American doctor to surrender his citizenship as a pre-requisite to Canadian medical licensure.

Requirements of Minnesota Basic Science Law

There are only four requirements to take the Minnesota Basic Science examination. They are as follows:

1. The applicant must be twenty-one years of age or over.
2. The applicant must be of good moral character.

3. The applicant must have an education equivalent to graduation from an accredited high school of this State.
4. The applicant shall pay a fee of $15.00.

The provisions of law pertaining thereto are as follows:

"Any person not hereinafter excepted from the provisions of this chapter desiring to practice healing in this state shall apply to the secretary of the state board of examiners in the basic sciences, on blank forms prepared and furnished by it, to be examined in the basic sciences at the next examination therein following the making of such application and for a certificate of registration in the basic sciences, accompanying such application with a fee of $15.00 and sufficient and satisfactory proof that the applicant is 21 years of age or over, is of good moral character and has an education equivalent to graduation from an accredited high school of this state; provided, that no applicant shall be required or requested to disclose in such application the professional college or university he may have attended nor the branch or system of healing which he intends to pursue. Examinations shall be in the basic sciences only and may be both written and by demonstration or other practical test, as the board may determine."

Sec. 146.06 Minnesota Statutes 1945.

You will note from the foregoing Section that the Basic Science Board is forbidden to make inquiry as to the college or university attended by the applicant or the branch of the healing arts that the applicant intends to pursue. There are two reasons for that provision being in the law; the first one is to prevent any discrimination as to an applicant who desires to practice osteopathy or chiropractic. The second reason is that the basic science law is merely a prequalifying examination in six subjects: anatomy, physiology, pathology, bacteriology, hygiene and chemistry. A basic science certificate does not authorize the holder to engage in the practice of healing. It does authorize the holder to then apply to either the Medical Board, the Osteopathic Board or the Chiropractic Board, depending upon the branch of the healing arts that the applicant wishes to engage in.

Fraudulent Foreign Medical Credentials

The problem of determining the authenticity of foreign medical credentials has plagued the various state medical examining boards throughout the United States for many years. In November, 1935, the following communication was sent by the Secretary of the California State Board of Medical Examiners to the Secretary of the Federation of Medical Boards of the United States:

"For several years I have been impressed with the ease with which may be obtained medical diplomas from various universities in foreign countries. We have in mind the case of —— ——, Los Angeles osteopath, who assertedly obtained a medical diploma from the University of Berne, Switzerland, dated July 16, 1924, after a very brief course, which we understand did not exceed *three months.* ——— ——— assertedly obtained a diploma from the University of Lausanne, Switzerland, *without attendance.* He also obtained a diploma from the University of Naples, after not more than *four months attendance.* ——— ———, a Missouri veterinarian, prominently mentioned in the diploma mill scandals of 1924, obtained a medical diploma from the University of Budapest, although according to the *American Medical Journal* of June 18, 1927, page 73, he was unable to pass their examinations.

"These are but a few of the many instances that have come to the attention of the California Board of the laxity with which foreign medical diplomas are issued.

"Our experience has developed that practically none of the foreign medical schools, including Scotland and England, keep any accurate check on the daily attendance of the student. It appears to be a kind of 'free and easy,' the only interest lying in whether the student was able to pass the final examination.

"Another feature is the established habit in Germany of students going from school to school, making it practically impossible for said students to file an accurate outline of their medical course, such as is required in this country.

"The Council on Medical Education and the Association of American Medical Colleges have placed heavy restrictions on the medical schools in this country and yet state boards are constantly faced with applications from graduates of foreign schools, who cannot file satisfactory evidence that they have completed a course of instruction equivalent to that required in a United States Medical School.

"When a student transfers from one U. S. medical school to another, he must show under the rules of the above mentioned organization that he has fully completed a course of study and received passing marks before he may be given advanced standing in the second school. This is not so, to my knowledge, in foreign schools.

"The undersigned has had experience with fraudulent documents purporting to be medical diplomas issued in Russia, Belgium and one or two other foreign countries. It is impossible to verify any medical credentials from Russia, particularly if issued prior to the present regime. The documents that emanate from Soviet sources cannot be accepted in any degree of confidence."

Suggestions for Meeting Temporary Needs of Foreign Medical Graduates

On an experimental basis from the standpoint of protection of the public health, it is doubtful if the problem of medical licensure of foreign medical graduates can be solved by simply amending the requirement of citizenship or the recognition of European medical schools. Since there is in existence no evaluating agency for the inspection and grading of European medical schools, it is necessary to examine the various articles that appear from time to time on this subject. In February, 1948, Dr. Irving S. Wright, Associate Professor of Clinical Medicine, Cornell University Medical College, New York, presented a paper on MEDICAL EDUCATION IN GERMANY AND AUSTRIA. Dr. Wright made a survey of medical education in Germany and Austria in 1947 with Dr. Edmund Horgan under the auspices of the Surgeon General of the United States Army. In his paper on that subject Dr. Wright said the following:

"It will be made clear from my discussion that there is a considerable discrepancy between the potentialities for medical education among the various medical schools of Germany and of Austria today, and this will be perpetuated until such a time as they are all in better position from the point of view of materiél and faculty. It now appears that this improvement will be slow to occur, and in some instances the universities may never achieve their former stature.

"There are five major facets essential to medical education; a well trained faculty; suitable buildings for the preclinical and clinical teaching, including hospital facilities; adequate supplies and equipment for the laboratories necessary to the training of the students and the carrying on of research; a patient volume load of sufficient size and variety to permit experience in a large number of diseases, and a well selected student body. All are vital. The faculty and the carefully chosen student body are the most important. Today, in Germany and Austria, the clinical material is the only ingredient which may be considered as adequate."

Speaking further on the subject of the destruction of medical buildings by bombing, Dr. Wright pointed out:

"Even two years later, at the time of our visit (University of Munich) major portions of the medical school remained heaps of rubble, and the surgical clinics were far from rebuilt. Large numbers of students crowded about in totally inadequate facilities, and relatively little active rebuilding was in process. * * * A similar report could be given in reference to most of the universities. * * * Chemical supplies are at a premium. It is perhaps symbolic of the high degree of destruction of scientific civilization when one finds that at the University of Munich, long famed for its fine chemical research, the determination of blood sugar studies is frequently impossible because of inadequate chemicals necessary for this simple test." * * *

"There is no penicillin available to the German hospitals; there is no streptomycin. Some sulfonamide drugs are available."

RESULTS OF EXAMINATIONS OF FOREIGN PHYSICIANS

(New York)

Year	Number Examined	Passed	Failed
1938	1,211	511	700
1939	1,770	521	1,249
1940	1,644	540	1,104
1941	1,558	575	983
1942-45 (incl.)	4,975	2,878	2,097
1946	315	106	209
	11,473	5,131	6,342

In discussing the large number of students enrolled in the medical school in Germany and Austria, Dr. Wright comments as follows:

"Appointment on political basis has resulted in tremendous overcrowding. For example in Vienna there were 3,500 medical students out of a total student body of 7,000. It was reported that at Munich there were 4,000 registered in the medical school, with 3,000 on the waiting list. Most of the other schools had from 1,800 to 3,000 medical students. Only the smaller ones had as few as 1,200. Inquiry indicated that the faculty members were inclined to believe that all of these students who so elected would eventually graduate. They have several opportunities to pass each set of examinations without being eliminated from medical school."

In his summary Dr. Wright stated:

"Medical education in Germany is at an extremely low level at this time. The Universities of Heidelberg and Wurzburg are the most satisfactory. Medical education in Vienna is somewhat better, but is handicapped by over crowding. * * * *Students graduating from these schools have not received a medical education comparable with that obtained in medical schools in this country.* This situation should be subjected to continuing analysis and recording by the boards of licensure so that in the future gradnates from these schools who apply for license to practice in the United States may be properly evaluated."

The Minnesota State Board of Medical Examiners at its last meeting decided to ask that this entire problem be made the subject of discussion at the annual meeting of the Federation of State

(Continued on Page 147)

MINNESOTA'S MATERNAL AND CHILD HEALTH PROGRAM

A. B. ROSENFIELD, M.D., M.P.H.
Minneapolis, Minnesota

TO acquaint the physicians of this State with the activities of the Maternal and Child Health Division of the Minnesota Department of Health, the following discussion is presented. All public health programs depend upon the wholehearted interest and co-operation of all agencies interested in health, such as the State Medical Association, the State Dental Association, University of Minnesota, the State Department of Education, as well as the voluntary agencies. It is particularly important that the medical profession be familiar with our objectives, our general program, the special problems involved and our results. Physicians need the assistance of health workers to help them in their professional work; public health requires the active and enthusiastic interest and support of all physicians to attain its objectives.

According to W. G. Smillie, Professor of Public Health and Preventive Medicine at Cornell University Medical School, "the most effective and the most important part of the community plan for promotion of the health of the individual, is the child health program." The younger the age group with which we work, the more effective will be the results that are achieved. While parents are unlikely to change their personal habits, they are quite willing to use the new knowledge of preventive medicine for the care of their children.

Our Objectives

1. To minimize risks of childbirth—disability and death.
2. To give each baby that is born the best possible chance of survival.
3. To help each child to grow up to maturity, as free as possible from any defect—physical, mental or emotional.

Requirements

1. Well-trained physicians for obstetrical care and pediatric care.
2. Well-equipped hospitals.
3. Antepartum and postpartum supervision.
4. Home nursing and public health nursing supervision.

There are three approaches to a public health program in maternal and child health: (1) prevention, (2) health education, and (3) medical care. In Minnesota the program is limited basically to preventive public health services and health education. Medical care is not included except for the federally financed Emergency Maternity and Infant Care program for the wives and infants of servicemen. The maternal part of the medical care was terminated July 1, 1948; the infant care program is now in process of liquidation and will terminate April 19, 1949.

Services rendered through Maternal and Child Health Division

1. *At State Level*
   - (a) Consultation and advice on maternal and child health programs and problems—(To other Divisions of the Health Department, PTA, Division of Social Welfare, Bureau of Crippled Children, State and County educational agencies, local Health Officers).
   - (b) Aid to local communities in developing sound plans and programs.
   - (c) Organization of groups for teaching maternal and child health classes.
   - (d) Promotion of distribution of literature and educational activities.
   - (e) Postgraduate courses in obstetrics and pediatrics for practicing physicians and nurses through co-operation with the University of Minnesota and professional groups.
   - (f) Special assistance in pediatric studies:
     Problems in hospital nurseries, premature program, acute infectious diseases, at request of hospitals or State hospital licensing unit.
   - (g) School health program—school health consultant assists in developing health services, health instruction, school sanitation, summer round-up, et cetera, in co-operation with ,State Department of Education and local schools.
   - (h) Financial subsidy—to public health nursing services:
     State subsidy to county public health nursing services ($1,500 per year).
     Federal subsidy ($1,000 per year for three years) for each new nurse added.
     Demonstration services to full-time health department and county nursing services.
     Indian nursing services.
2. *Nutrition Unit*
   Improvement on food and nutrition practices of expectant and nursing mothers, infants, growing children, workers in industry and other adults in family:

Dr. Rosenfield is Acting Director—Division of Maternal and Child Health Minnesota Department of Health.

By development and promotion of use of education information and methods.
By providing consultation to public health and allied workers.
By direct service through talks to groups and conferences on demonstration basis.

Our first problem is maternal health. If we are to maintain our low maternal death rate, we cannot become complacent but must continue and intensify our efforts. We must emphasize the importance of good and adequate prenatal care, obstetrical care, and proper postnatal care by physicians well trained in obstetrics, in well-equipped hospitals with modern facilities for the delivery of babies. Of Minnesota's 75,468 births in 1947, 96.7% occurred in hospitals, and only 3.3% were home deliveries.

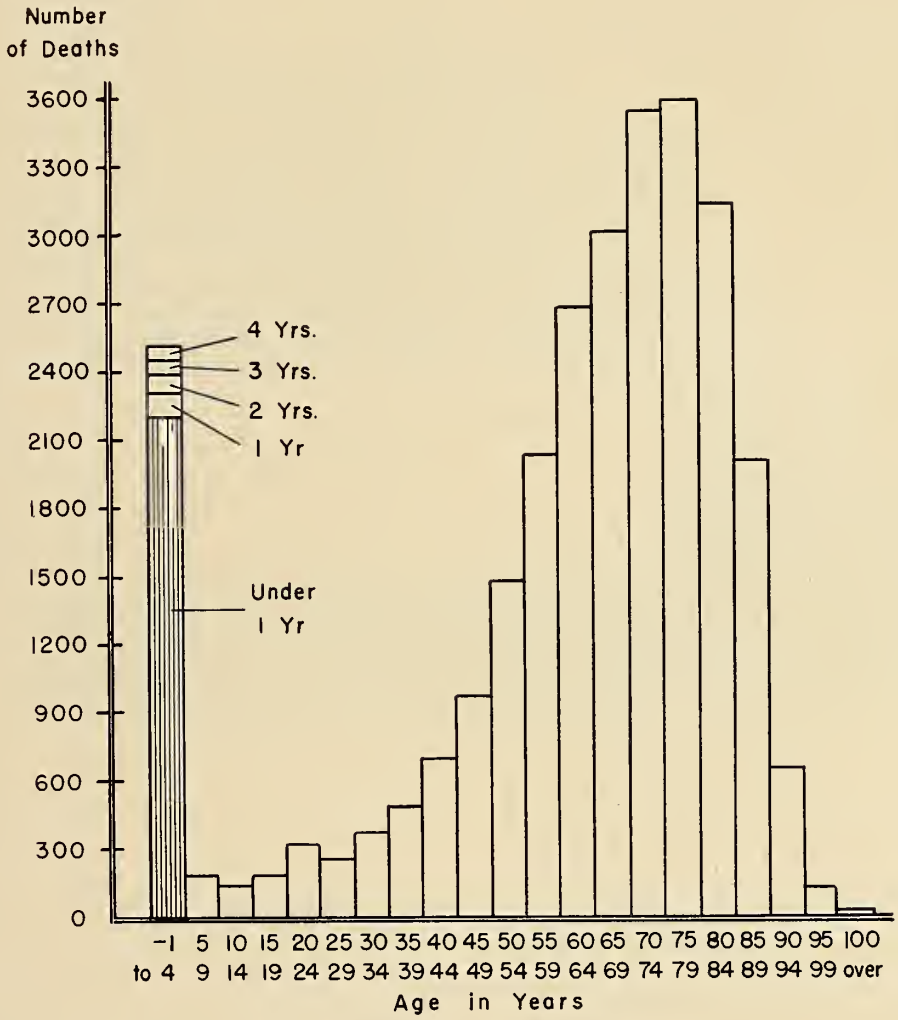

Fig. 1. Total deaths, by age, in Minnesota—1947.

3. *State District Health Offices*
   (a) Advisory nurse gives consultation, advice and supervision to local public health and school nurses on maternal and child health program planning, promotion of distribution of literature and other educational activities, promotion of classes, and loan of audiometers for hearing testing programs.
   (b) Nutritionist gives consultation service to public health and school nurses, prepares and conducts nutritional education program.

Now let us consider some of the specific problems in a Maternal and Child Health program.

Our efforts are directed to assistance in prenatal and postpartum clinics where they have been established. Advisory nurses of the Health Districts give advice and consultation and supervision to local public health nurses in the field. A maternal and child health nurse consultant as-

sists advisory and field nurses and hospitals in developing programs throughout the State, assists in county problems such as high infant mortality rates, gives demonstrations, holds classes and

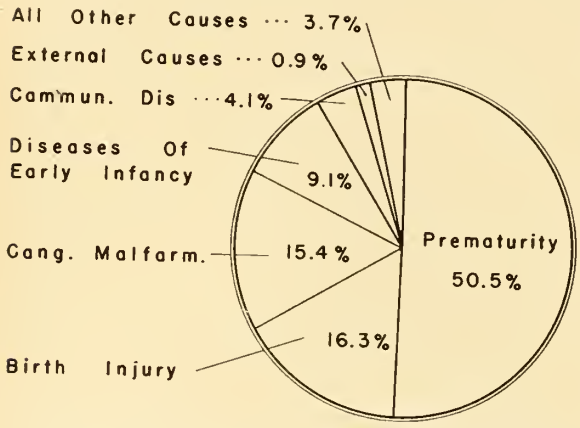

Fig. 2. Distribution of the cause of death of 9,373 infants reported dying in the first month of life in Minnesota—1941-1947, inclusive.

meetings, gives radio talks, and distributes authoritative educational literature. Films and exhibits are also available. Our nutrition program is devoted to the improvement of food and nutrition practices of expectant and nursing mothers, infants, growing children and adults. It provides consultation to public health and allied workers and carries out an educational program by talks, exhibits and literature. In addition, studies on food consumption of pregnant women as well as studies in co-operation with dental surveys in schools are being carried out. Postgraduate courses for physicians are given periodically, in co-operation with the State Medical Association and University of Minnesota, to bring the latest scientific information to them. A three-day course on obstetrics, premature and newborn care for general practitioners, will be held soon at the Continuation Center with all expenses paid for those selected by medical societies to attend the course. Study of causes of deaths of mothers so that adequate steps may be taken to reduce them even lower than they are now, will be carried out jointly by the State Medical Association and the State Department of Health.

Neonatal deaths constitute one of our most serious problems. While infant mortality has declined markedly from 70 per 1,000 live births in 1915 to 28.6 in 1947, the decrease of 59 per cent has occurred from the age of one month to one year and not in the first thirty days of life. It is of interest to note that the total number of deaths under the age of one year is greater than the total deaths occurring from age one through age thirty-five. This total is not reached again until the five-year period from ages fifty-five to sixty years (Fig. 1). The major causes of neonatal deaths are prematurity, birth injuries, malformations and infections, as shown on the pie diagram which gives the actual percentages during the past seven years (Fig. 2). These deaths constitute 73 per cent of all deaths occurring under the age of one year.

Prematurity is responsible for one-half of the neonatal deaths. It is also in this group of deaths that the possibility for continued reduction in infant mortality lies. Prematurity was the ninth leading cause of death in Minnesota in 1946 and 1947, while tuberculosis ranked as the tenth leading cause of death. To reduce these deaths, we must continue to emphasize the importance of better medical and nursing care by instruction of local physicians on the latest practice in obstetrics and infant hygiene by short courses at the University; instruction of local public health nurses in hygiene of maternity and infant care with continuous supervision of their work; instruction of newborn and premature nursery supervisors and nurses in modern techniques and standards of hospital practice; instruction to mothers in simple principles of infant hygiene, as well as adequate prenatal care, by classes, pamphlets, letters, radio talks and personal conferences; adequate facilities for care of premature infants—hospitals, incubators, trained nursery personnel, modern hospital and nursery standards and practices. There should be available consultation by a pediatric nursing consultant or pediatrician to help reduce infant deaths by teaching hospital nursing techniques and standards, as well as diagnosis, treatment and prevention of pediatric problems such as premature care, birth injuries and communicable diseases.

During infancy there must be emphasis on protection from communicable disease. During 1947 there were twenty-five deaths from whooping cough under the age of one year, seventeen deaths from measles at all ages, and twenty deaths from diphtheria at all ages, with 37 per cent under the age of five. Too much emphasis has apparently been placed on preschool immunization and not enough on the importance of early protection,

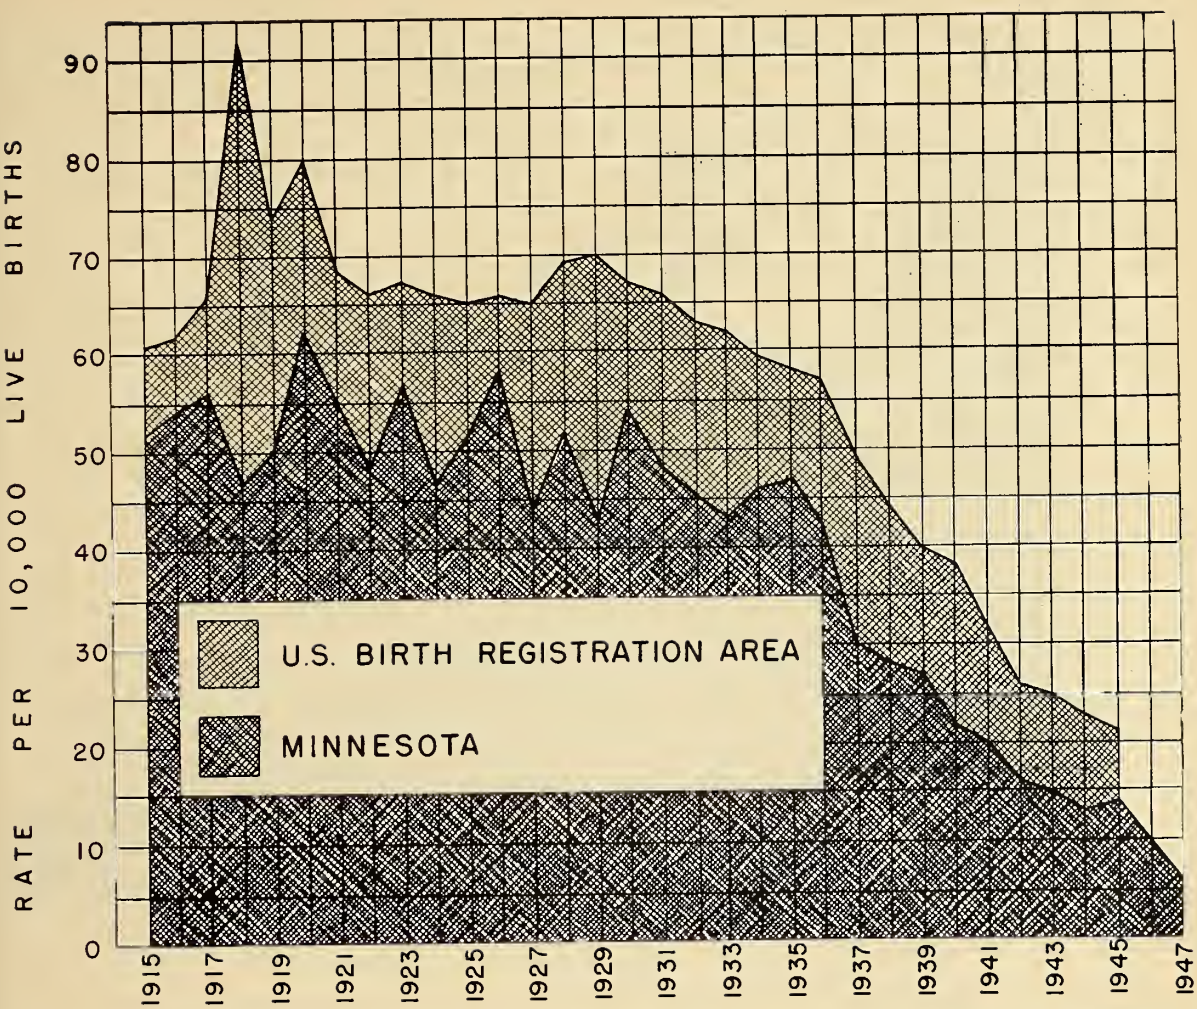

Fig. 3. Comparison of maternal death rate per 10,000 live births in Minnesota with those in the United States Death Registration Area—1915-1947.

during infancy. Most physicians insist that their infant patients are well protected in their practice. Yet our studies indicate that, in general, considerably less than 50 per cent of the children are fully protected by the age of five, on entrance to school. Early vaccination and immunization for whooping cough, diphtheria, tetanus and smallpox are necessary and should be completed by the age of one, with booster doses as indicated. Biologics for vaccination, immunization and treatment are available on request, free of charge. There should be periodic examinations of infants, proper feeding and food habits and mental hygiene with good habit training, through private physicians, public health nursing supervision and community health centers.

The preschool child requires health protection and the prevention of communicable diseases by immunizations and vaccinations, public health nursing services in the home, establishment of sound nutritional food habits, good habit training and mental adjustment to life situations, provisions for detection of incipient disease, the correction of physical defects and dental care.

At the school age level, in co-operation with the State Department of Education and local schools, child health requires emphasis on modern standards and techniques for school health services, modern teaching material on health and consultation service on medical examinations made by local physicians. A "School Health Manual" jointly prepared by the State Department of Education and the State Department of Health was recently published. It has been well received by educational and health workers in Minnesota as well as in a number of other states. A nutrition program for the development of good food habits in children, a program for the correction of de-

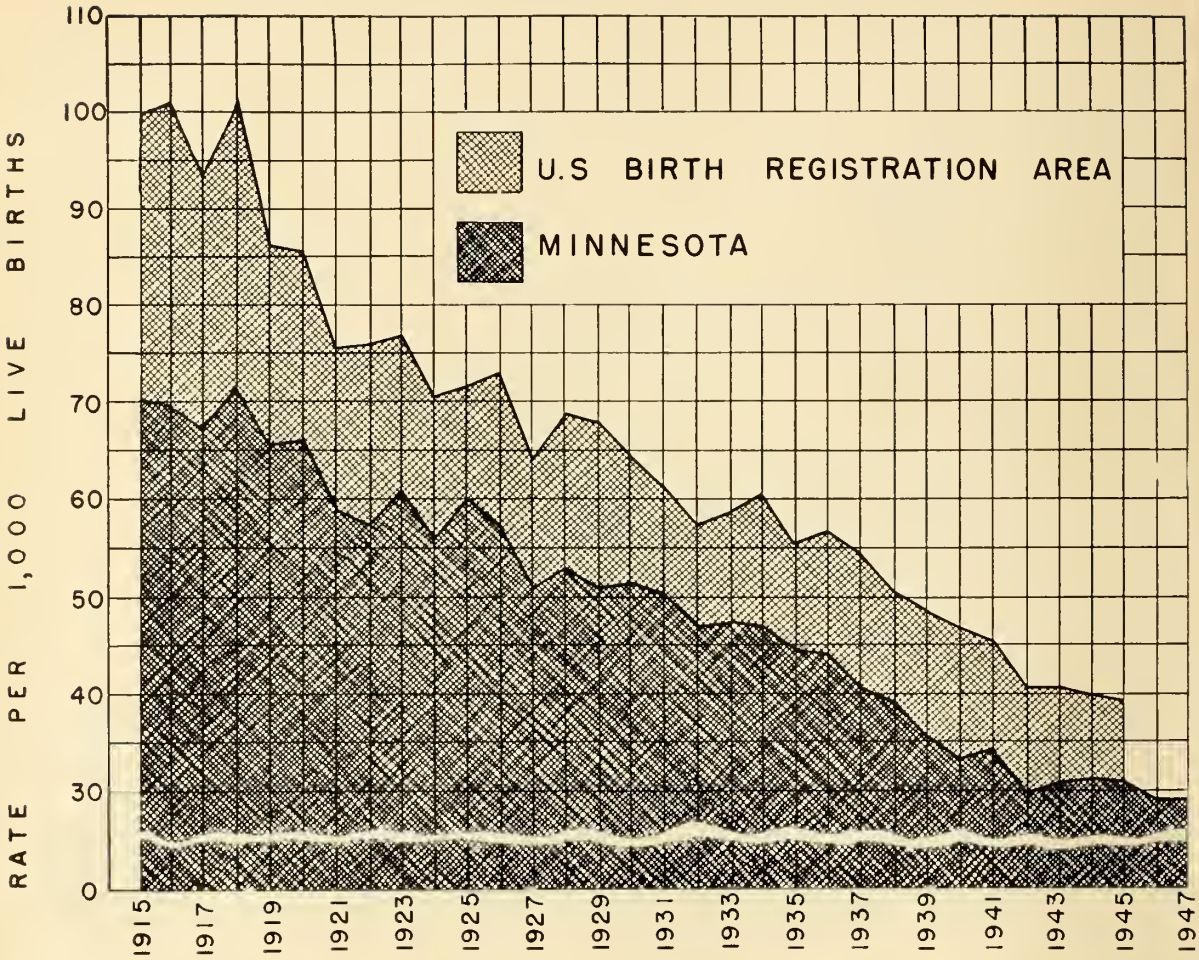

Fig. 4. Comparison of rate of deaths under one year of age per 1,000 live births in Minnesota with those in the United States Birth Registration Area—1915-1947.

fects by available community resources and in-service training for teachers on health is essential. The establishment of school health councils as a part of county or community health councils is important. One special problem in this age group must be mentioned. Accidents are the leading cause of death between the ages of one and fifteen, and an outstanding cause of disabling and permanent injuries among children. Of the 1947 accidental deaths in Minnesota in 1947, 284 occurred between birth and 15 years of age. Notwithstanding the work of various groups in the schools and elsewhere on accident prevention and safety, results are not significant and the death rate stays high. The child accident mortality rate shows a much smaller decline than does the rate for any of the other causes of death among children. A school educational program is being developed, designed (1) to recognize the accident hazards confronting young children; (2) to provide and maintain safe conditions for the child in the home, school and playground; and (3) to help the child to develop safe practices through proper example and guidance.

Of the special studies being carried out in our maternal and child health program, one in particular should be mentioned. For the past year a study on methemoglobinemia in infants has been in progress. Approximately 100 cases have been reported and investigated. This condition has occurred during the first three months of life in infants who were fed on diluted milk formulae, using water with high nitrate content, from poorly constructed farm wells. The usual symptoms are lethargy and cyanosis, occasionally with diarrhea, and the blood is chocolate colored. There have been ten deaths. To confirm the diagnosis we have available an electric photometer and are prepared to

examine the infant's blood for methemoglobin, on telephone request to our office. A brief description of the occurrence, diagnosis and treatment of this condition was recently mailed to all physicians.

As an evaluation of our results let us consider for a moment our infant and maternal mortality rates during the past thirty years. The maternal mortality rate for Minnesota in 1915 was 52.0 per 10,000 live births; the U. S. rate was 61.0. In 1945 the rate for Minnesota was 14 per 10,000 live births while the U. S. rate was 21.0. In 1947 the rate in Minnesota dropped to 6 per 10,000 (47 maternal deaths in 75,468 live births). The U. S. rate for 1947 is not yet available but our rate is one of the lowest, if not the lowest, rate in the United States. (Fig. 3).

Our infant death rate in 1915 was 70.1 per 1,000 live births while the U. S. rate was 99.9. In 1945 our rate was 31.6 per 1,000 live births in comparison with the U. S. rate of 38.3. In 1947 the Minnesota rate dropped to 28.6, among the lowest in the country. (Fig. 4). It is of interest to note the variation in rates by counties. One Minnesota county had an infant death rate of 5.1 per 1,000 live births but other counties far exceeded our state rate. The highest rate in 1947 in one county was 61.6 indicating the necessity for special study as to cause and possible prevention.

The stillbirth rate has decreased similarly from 29.0 per 1,000 live births in 1915 to 17.4 in 1947. In comparison, the U. S. rate in 1915 was 39.4 while in 1945 it was 23.9.

While our maternal and infant death rates continue to be among the lowest in the United States, it should be possible to reduce our infant deaths still further. Continued close co-operation between physicians and the Division of Maternal and Child Health will result in better health for our mothers and children.

FOREIGN MEDICAL GRADUATES

(Continued from Page 141)

Medical Boards to be held in February in Chicago. The Minnesota State Board of Medical Examiners is of the opinion that a committee of not less than four doctors make a survey of all the medical schools in Europe where such a survey will be permitted by governmental authorities, the committee to have at least one member from each of the four following groups:

1. The Federation of State Medical Boards.
2. The Association of American Medical Colleges.
3. The United States Veterans Administration.
4. The Council on Medical Education and Hospitals of the American Medical Association.

Such a committee would then be in a position to make available its actual findings and recommendations to all of the state medical examining boards throughout the United States. A representative of the United States Veterans Administration is suggested for the reason that at the present time a considerable number of American citizens who served in the Armed Forces of the United States are studying medicine in European medical schools. A large portion of this group will undoubtedly return to the United States desiring to practice medicine.

PREFRONTAL LOBOTOMY FOR THE RELIEF OF INTRACTABLE PAIN

J. GRAFTON LOVE, M.D., MAGNUS C. PETERSEN, M.D., and FREDERICK P. MOERSCH, M.D.

Rochester, Minnesota

IN 1936, Egas Moniz and Almeida Lima, of Lisbon, Portugal, reported the results which they obtained with prefrontal lobotomy in the treatment of certain mental diseases. In 1937, Freeman and Watts,[4] of Washington, D. C., reported the results which they obtained with this treatment in a similar group of cases. Since that time, prefrontal lobotomy has come to be generally recognized as a suitable form of treatment in certain types of mental illness when more conservative measures have failed to produce permanent results. It has been estimated by Freeman and Watts[7] that lobotomy has been performed approximately 2,000 times in the United States since this method of treatment was introduced in 1936.

It is no more than natural to learn that this operation has been found to have some contraindications as well as indications in conditions other than those of mental disturbance. Many patients who are mentally disturbed complain severely and bitterly of pain, which we consider to be functional in origin, in some particular part or organ of the body. Since these patients have been relieved by prefrontal lobotomy, it was only natural to consider the possibility that prefrontal lobotomy might relieve intractable pain of organic origin. This has been found to be true.

More and more often one hears of patients who have been relieved of intractable pain by prefrontal lobotomy. Freeman and Watts,[5,6,11] Poppen, Golla and others have written on the subject of relief of pain by prefrontal lobotomy. Davidoff of New York and Murray Falconer of New Zealand have told one of us (J. G. L.), in personal communications, of the performance of prefrontal lobotomy for intractable pain. We have been interested in prefrontal lobotomy in the treatment of mental disease for several years. One of us has performed this operation in cases of intractable pain, and a discussion of these cases will be presented in this paper.

At first we were loath to advise prefrontal lobotomy for pain alone just as earlier we were hesitant about performing prefrontal lobotomy for psychosis. As the years have passed and results from prefrontal lobotomy in mental disease have been so promising we have been encouraged to attempt the operation for intractable pain. At first, the operation was used for intractable pain of organic orgin associated with mental disease. Subsequently, prefrontal lobotomy has been used in the treatment of organic pain and "functional" pain in cases in which there was no psychosis. We have come to have the feeling that Freeman and Watts have so well expressed as follows: "In many cases the attitude of the patient toward his disease is more disabling than the disease itself; the fear of pain is greater than the pain. With prefrontal lobotomy the physician now has it in his power to relieve the fear, the anticipation and to render the illness more tolerable to the patient. Since this can be done without significant impairment of intellectual capacity, it would seem that prefrontal lobotomy might be a very considerable boon to the large number of patients whose lives will not be long but will nevertheless be made miserable by suffering."[7]

It should be added, also, that peace and happiness and concern of the family as well as the condition of the patient should be considered. Many of the patients suffering from intractable pain and particularly those who are dying of an inoperable malignant lesion cause a great deal of suffering among their friends and relatives and present a considerable burden because of the care which they must have. If their pain can be relieved by prefrontal lobotomy and their mental outlook on life changed to a more cheerful one, the problem of care during their last weeks and months of life is considerably lessened.

Although prefrontal lobotomy is a relatively simple operation to perform and although it can be performed in most cases with the patient under local anesthesia, it should not be recommended nor carried out without careful and due consideration, for of course it is a destructive procedure and the effects of the operation cannot be overcome; that is, the pathways which have been interrupted by the leukotome cannot be reestablished. Consequently, the disadvantages as well as the advantages of the procedure should be discussed very carefully with the patient in most cases and with the family in all cases, so that there

may be no misunderstanding if the results are not what one would anticipate. All too often when a surgical procedure is recommended or offered to a patient and his relatives, they of course, being human, expect or at least hope that the operation will result in cure. It is necessary in these cases to make it plain that the operation is performed in an attempt to relieve the patient of his pain and suffering and that it cannot possibly result in cure of the underlying disease which has been producing the intractable and unbearable pain.

Not only is the relief of pain one of the primary considerations for carrying out a prefrontal lobotomy in the patient suffering from incurable disease associated with severe pain, but the fact that when the pain or consciousness of pain is relieved, the use of narcotics is no longer necessary. Most of these patients who have been taking narcotics for a long time are troubled with constipation, indigestion and other disturbances of bodily functions. When the pain has been relieved and the use of narcotics is no longer necessary, the bodily functions proceed on a more normal basis, and this also gives peace of mind and comfort to the patient and to the relatives.

The technique which we used in the cases reported is that described by one of us in 1943.[9] A grade 3 operation was performed in each case.

Report of Cases

Case 1.—A widow, seventy-one years of age, was referred to a neuropsychiatric consultant at the clinic with a diagnosis of neuritis of an undetermined origin. The referring physician stated that the patient was having considerable pain the relief of which required large doses of sedatives. The patient registered at the clinic on July 8, 1946. She stated that on August 17, 1945, while sewing, she pricked her right thumb. The next day the thumb was swollen and red. There were vesicular lesions on the dorsum of the right hand and outer surface of the right arm. These lesions spread and involved the entire right arm and forearm. She experienced very severe pain which was still present when she came to the clinic. She described the pain as like that of knives twisting in her extremity. At the time of onset she was confined to a hospital elsewhere for ten days. The vesicular lesions disappeared; they were said to be those of "shingles."

Subsequently, the patient had a "nervous breakdown." On September 1, 1945, she was hospitalized elsewhere for one week because of continued pain, insomnia, nervousness, anorexia and mental depression. On October 15, 1945, she was hospitalized in a sanatorium because of the same complaints. She was given four electrotonic treatments which relieved the insomnia but had no effect on the pain; her mental condition was said by her only surviving relative, a son, to have been improved greatly.

On January 15, 1946, the pain increased. Insomnia developed again with mental depression. The patient stated that she did not want to live. She was again hospitalized and while in the hospital she was discovered out on the balcony ready to jump. On April 1, 1946, she was hospitalized in another sanatorium. She was given nine electrotonic treatments. These again gave her considerable relief from the insomnia, nervousness and depression, but the pain became worse. At the time the patient was admitted to the clinic, the insomnia was returning and she was taking large doses of sedatives. The patient also complained of tightness in her head which she described as a headache. Further, she stated that she felt as if there was a band around the frontal and occiptal regions of the head. A diagnosis of postherpetic neuralgia with reactive depression was made.

The patient's blood pressure was 140 systolic and 80 diastolic, expressed in millimeters of mercury. The general physical examination gave normal results for a patient of her age. A neurologic examination revealed that the right biceps reflex was less prompt than the left. The deltoid, biceps and triceps muscles on the right side were slightly weaker than the corresponding muscles on the left side. There were no other neurologic findings.

Prefrontal lobotomy as a method of treatment both for the reactive depression and for the postherpetic neuralgia was offered the patient and her son. The indeterminate prognosis was carefully explained to them. After thinking the problem over, the patient came back to the neuropsychiatric consultant in a happy mood because we had offered something that she thought would be beneficial to her. The son stated that he wished the operation performed because he was afraid that if we did not operate, his mother would commit suicide. On July 17, 1946, a bilateral prefrontal lobotomy, grade 3, was performed with the patient under local infiltration anesthesia.

The patient's convalescence was prolonged owing to the fact that she showed a moderate degree of confusion after the operation, and it was necessary to restrain her because she could not control the bladder and bowel satisfactorily. The sutures were removed from the incisions in the skin on the fourth postoperative day. Up until the last week of her stay in the hospital she was disoriented for place, but she was well oriented for time and person. At the time the patient was dismissed from the clinic on August 17, 1946, she had regained her orientation for place, the bowel and bladder habits were re-established, the patient no longer complained of pain and her depressed status had dramatically disappeared. No sedative whatever was required after the operation.

Case 2.—The patient first registered at the clinic on April 25, 1938, at which time he was forty years of age. His chief complaint was pain on the left side of the face and head. The patient stated that when he was eighteen years of age he had had a tonsillectomy and adenoidectomy to improve the hearing in his right ear.

He had had chronic otitis media since childhood and he could not hear with the left ear. While in college he had an appendectomy and multiple sinus and nasal operations. He had had the ethmoid, sphenoid, frontal and maxillary sinuses all operated on and all had drained repeatedly. A submucous resection also had been performed.

About 1928 or 1929, he started having trouble with pain in his face and head. The onset of the pain in the left side of his face and head, which was his chief complaint, was in 1929. He had repeated injections of alcohol into various branches of the trigeminal nerve on the left side. He had a resection of the peripheral branches of the maxillary division with no relief. In 1932, he had a resection of the sensory root of the trigeminal nerve on the left side. His pain was relieved but he still had trouble. Then he had a radical left mastoidectomy.

In 1934, the trigeminal nerve was operated on again. Technical difficulties were encountered apparently, and six weeks later the surgeon elsewhere re-entered the temporal area and divided some fibers, with no benefit to the facial pain. He had more injections of alcohol in 1936. Later, another surgeon removed the cervical plexus of nerves on the left for pain, but the pain was unaltered. With increased pain the patient stated that he would faint. He never hurt himself and the syncopal attacks always occurred at home or under emotional strain.

Neurologic examination disclosed that the left corneal reflex was absent. There was anesthesia over the distribution of the left trigeminal nerve. The motor component of the left trigeminal nerve was intact. No further surgical treatment was advised at that visit to the clinic.

The patient returned to the clinic November 13, 1946, stating that his facial pain had continued after his previous visit. In June, 1938, he had gone to another institution and had had a left transtemporal operation. After this operation, the patient was relieved of his syncopal attacks but pain was unaltered. In March, 1946, there had been a sudden onset of continuous hiccough night and day. Nothing would give the patient relief. He had had general anesthesia on occasion in order to stop the hiccough. Simultaneously, bilateral occipital headaches developed, with radiation to the right facial area. He would have, on an average, three such attacks per week, and the attacks would last for twenty-four hours. The attacks would awaken the patient at night. They were made worse by coughing, sneezing and straining.

Examination at the time of his return to the clinic revealed weakness of the muscles innervated by the motor branch of the left fifth cranial nerve, persistence of corneal anesthesia and complete anesthesia in the region of the sensory distribution of the left fifth nerve. Because of chronic drainage from the right ear due to otitis media, a radical mastoidectomy on the right side was performed on November 22, 1946. This operation failed to give the patient relief from his pain. Tetraethylammonium chloride was cautiously administred intravenously with no change in the pain in the patient's face and no change in his hiccough. In fact, the observer felt that the hiccough may have been made a little worse. One of us (J.G.L.) was asked to see the patient regarding the performance of a bilateral prefrontal lobotomy in an attempt to relieve him of the distressing pain-in-the-face syndrome. It was hoped, also, that the operation might be beneficial in relief of the hiccough. Without a promise of any benefit, the patient was offered the procedure on an optional basis. He went home, considered the matter and returned requesting that the operation be performed, since he continued to have the severe pain in the face and hiccough.

On February 3, 1947, with the patient under general anesthesia at his own request—usually the operation is performed under local anesthesia—a bilateral prefrontal lobotomy, grade 3, was carried out without incident. Although the patient had been accustomed to taking large doses of sedatives, he required no sedatives after the operation. When he was dismissed from the clinic on February 19, 1947, his head wounds were well healed. While in the hospital he experienced the development of a lesion characterized by extensive brawny induration of the left thigh which was incident to previous self-medication. After the lobotomy the patient experienced relief from the pain in the face and from the hiccough.

Case 3.—A white woman, seventy-two years of age, came to the clinic in May, 1947, because of burning pain in the bladder. Her husband had died eleven years before from a stroke and disease of the prostate. She had one son living in fair health and one daughter living and well. At that time we got a history that the patient had had a severe attack of cystitis about forty years before. The cystitis had followed a bad cold. A cystoscopic examination on May 30, 1947, revealed only a small clear cyst in the urethra at the 10 o'clock position. This cyst was considered of questionable clinical significance. The rest of the general examination gave entirely negative results. Also neurologic examination gave negative results. The patient was moderately depressed. She was referred to a psychiatrist who had treated her previously. Previously she had been treated with electrotonic therapy elsewhere in a mental hospital and after two months she had felt quite well. Later she had been hospitalized again for three months, during which she had received fifteen electrotonic treatments. As a result, she apparently had become well and had been able to take care of the house. The benefit from the electrotonic treatments had not, however, been sustained.

In June, 1947, the patient began to have pain in the bladder, became nervous, unable to sleep and depressed and she felt like crying continuously. At that time, she requested admission to a mental hospital on voluntary application; she was admitted on July 24, 1947. A physical examination gave essentially normal results. The blood pressure was 134 systolic and 80 diastolic. The neurologic examination showed an increase in the reflexes. No abnormal reflexes were noted. The results of serologic examination of the blood and spinal fluid were normal. Mentally, the patient was depressed and she was very anxious to have electrotonic treatments.

It was the opinion of one of us (M.C.P.) that such treatments might help temporarily, but he advised that a prefrontal lobotomy would be more advisable. The patient was very anxious to have this operation performed. She stated that life was unbearable to her the way she felt at that time. The patient and her son both requested that the operation be performed. A diagnosis was made of agitated depression and indeterminate bladder pain, for which the patient underwent a bilateral grade 3 prefrontal lobotomy on August 13, 1947.

Eight months after operation the patient had no bladder pain and her agitation had completely cleared up.

Case 4.—A white man, thirty-seven years of age, registered at the clinic on January 29, 1945. His chief complaint was of pain in both hands for which he previously had had a bilateral sympathectomy. He presented a very difficult problem. It was the opinion of a consultant in the section on vascular diseases that the pain was not on the basis of a vascular disease; he preferred instead to classify it as a causalgia. The patient had been taking morphine for two years but said that he took it only for relief of pain; he had gone without morphine for as long as six days during the past month. The onset of his pain had been bilateral in the tips of the second, third, fourth and fifth fingers.

After sympathectomy the patient obtained complete relief on the left side and complete relief on the right for a period of two months; then there was recurrence of pain and added trigger areas over the back of the elbow and the upper scapular region. There was a postoperative Horner's syndrome on the right. The results of neurologic examination were essentially normal, except for some atrophy of the right suprascapular muscle. Cutaneous sensation in the right upper extremity could not be tested accurately because touching the hand would set off severe paroxysms of pain. A sweating test done with the aid of a baker on December 6, 1945, revealed sweating throughout the skin area of the chest, the left upper extremity and the left side of the face. There was no sweating on the right side of the face or over the right shoulder and the anterior surface of the right arm. On December 10, 1945, a bilateral cervicothoracic sympathetic ganglionectomy and trunk resection according to the Adson technique through the first rib was performed for the causalgia. Immediate relief of pain was obtained, the patient could shake hands, his skin was not hypersensitive and he was able to give up his sedatives. On December 19, 1945, a postoperative sweating test done with the aid of a baker revealed complete absence of sweating over the head, face, both extremities and upper part of the chest.

The patient returned to the clinic June, 1946, stating that after the bilateral cervicothoracic sympathetic ganglionectomy he was perfectly well for three and a half months. His hands were painless. They were constantly warm and dry. He was about ready to return to work. At that time, however, he had an abscessed tooth which required extraction. After this, he began to have recurrence of pain and hypersensitivity of the distal two-thirds of the left second, third, fourth and fifth fingers which spread to involve the same fingers of the right hand after six or eight hours. He stated that the only thing that would give him relief was morphine sulfate.

Fig. 1 (Case 4). Contractures of palmar fasciae resulting in Dupuytren's contracture.

On examination, nothing special could be noted except that a Dupuytren's contracture of each hand was developing. A sweating test performed on June 19, 1946, revealed an absence of sweating except over a small area of the anterior surface of the left arm and along the ulnar side of the left forearm. Another sweating test was done July 29, 1946, and at this time there was definite sweating in both hands, some in both arms and considerable on the left forearm. At this time it was felt that no further nerve operation would be done. The patient was given a trial of treatment with diphenhydramine hydrochloride (benadryl) and histamine, neither of which benefited him. He was taking, on an average, ¼ grain of morphine four times a day.

Since the sweating test showed that there was some sympathetic innervation getting through to the upper extremities, on August 5, 1946, a bilateral anterior approach to the cervicothoracic sympathetic system was carried out. The scar tissue at the site of previous removal of the stellate ganglia on December 10, 1945, was explored carefully and the scar tissue was resected. The pathologist found, on microscopic examination of the scar tissue, some sympathetic nerve tissue of a neuromatous type, and one small ganglion cell station was identified on the right side. After this operation, the patient was free of pain, and sweating was abolished from the upper extremities again.

However, after the patient had been at home for about three weeks, doing very well, the pain in the finger tips started again. The patient stated that the pain this time was worse than it had ever been. The pain was aggravated by changes in temperature and by nervousness. The pain this time was located not only in the fingers but in the hands. The thumbs still were not involved. The patient this time had rather severe contractures of the palmar fascia of both hands (Fig. 1). He was taking 2 to 3 grains of morphine a day. His wife, a registered nurse, had to dress and undress him and had to feed him as his hands were so sensitive that he was unable to do anything for himself. In spite of the

good care his wife was giving him, he was losing weight and appeared cachectic (Fig. 2). A sweating test revealed just the slightest amount of sweating over the palms

Fig. 2 (Case 4). (*a*) Posterior view showing marked wasting as a result of severe pain and excessive use of opiates which were required for relief of pain. (*b*) Anterior view showing pinched facies and dejected appearance.

of each hand. It seemed to all of us who saw the patient that nothing short of a prefrontal lobotomy was likely to relieve him. The situation was discussed very frankly with the patient and his wife. They were told of the advantages and disadvantages. They both requested that the operation be performed.

On July 16, 1947, with the patient under local anesthesia, a bilateral prefrontal lobotomy, grade 3, was performed for bilateral intractable pain in the hand. After the bilateral prefrontal lobotomy, the patient obtained complete relief from his pain and required no sedation. A sweating test performed July 24, 1947, two days before dismissal, revealed the slightest amount of moisture in the palms of both hands. The patient was dismissed from the clinic on July 26, 1947, smiling (Fig. 3) and no longer having the appearance of dejection and depression. A letter received from the patient's wife on November 17, 1947, stated that she was having considerable difficulty with the patient who presented a behavior problem. The wife stated further that he now weighed 150 pounds (68 kg.) and looked wonderful but that he was having temper tantrums and that it was difficult for her to cope with the situation. She did not state whether or not it was necessary to give him any sedative. She stated that at times he did have some pain in the right hand. Institutional care was recommended.

Case 5.—A white woman, aged fifty, had a bilateral prefrontal lobotomy, grade 3, on November 28, 1947, because of intractable pelvic and peritoneal pain, secondary to malignant disease. This patient had undergone a combined abdominoperineal resection for carcinoma of the lower part of the rectum on August 2, 1943. The tumor was at the anal margin and was a grade 1 colloid carcinoma 3 cm. in diameter, with perirectal extension. This patient was a local person who had been under observation at the clinic for many years. At the time she was readmitted to the hospital, she was found to have recurrent metastatic carcinoma of the rectum with perineal and pelvic masses and some fullness of the liver. She was suffering from excruciating pain which required $\frac{1}{16}$ grain of dilaudid (dihydromorphinone hydrochloride) every two hours. Radium therapy had failed to control her pain. One consultant made a note that all manner of sedatives had been given without particular effect. He recommended a trial of large amounts of vitamin C, 500 mg. a day, and the use of cobra venom. Among the sedatives and narotics used were dilaudid, pantopon, demerol hydrochloride (merperidine hydrochloride), morphine and codeine. Each in turn seemed to lose its effect within a short time.

In an attempt to relieve this patient of her pelvic and perineal pain, diagnostic and therapeutic injections of metycaine hydrochloride and dolamine were given. Injections were given paravertebrally and into the sacral canal. The relief obtained from the use of dolamine was of relatively short duration. Finally, because the patient could not eat, was suffering from constipation, was vomiting and was experiencing severe pain which could not be controlled with usual narcotics, a prefrontal lobotomy was considered as a palliative procedure to relieve her of her pain, particularly because she had become so depressed that she was considering self-destruction in order to get relief.

On November 28, 1947, with the patient under general anesthesia produced by pentothal sodium (sodium 5-ethyl-5-(1-methylbutyl)thiobarbiturate) given intravenously, a grade 3 bilateral prefrontal lobotomy was performed without incident. After the operation the patient was free of pain, she could eat without nausea and vomiting and her bowels began to move normally; in fact, a diarrhea which necessitated the administration of codeine developed. Her expression changed from one of depression to one of happiness. She took an interest in current affairs and liked to visit with many of the staff whom she had known very well. For thirteen days following the operation, she was free of

pain and required no sedative. On the evening of the thirteenth postoperative day, after an uneventful convalescence and after advice that she could go home, she became upset and it was necessary to institute sedative therapy. This upset occurred because the situation at her home was such that she could not return there.

The patient continued to receive relatively small doses of an effective sedative until her death sixty-one days after prefrontal lobotomy. During the time she was in possession of her faculties, she took care of herself and enjoyed visits from the doctors and her friends. An interesting postmortem finding in addition to the widespread carcinoma was a large duodenal ulcer which had perforated onto the anterior abdominal wall and which had not been recognized during life.

In addition to the five cases which we have reported in more or less detail, we have had four other patients that underwent bilateral prefrontal lobotomy for intractable pain.

Case 6.—One man, aged thirty-three, had bilateral prefrontal lobotomy because of the excruciating pain of diabetic neuritis. This man had lost his vision because of diabetic retinitis and, as a result, attempted to take his life by slashing his wrist. This patient's diabetes could not be controlled, and he died several weeks after operation. It is questionable if anything worth while was accomplished for him.

Case 7.—A man, aged fifty-five, who had experienced a cerebrovascular accident and who was troubled with severe and disabling headache underwent prefrontal lobotomy for the headache because his wife and daughter felt that he would commit suicide if no treatment were given. After the operation, he was much happier and had little distress, but he became difficult to handle. He became definitely antagonistic and abusive; this condition was present prior to his coming to the clinic, but we had not known of it. He was relieved completely of his headache after the operation.

Case 8.—A woman, aged seventy, had become incapacitated for her duties as a teacher because of pain in the anesthetic area of the right fifth cranial nerve and at the site of craniotomy for division of the posterior root of the trigeminal nerve for trigeminal neuralgia. The patient not only could not concentrate, but she was making life miserable for those people around her. Bilateral prefrontal lobotomy relieved her of pain; she then could smile and enjoy life whereas she had had the appearance of abject depression before operation.

Case 9.—A white woman, seventy-three years of age, with extensive and marked arteriosclerosis who was bedridden and addicted to the use of narcotics because of intractable bilateral sciatic pain secondary to spinal arthritis of many years' standing was completely relieved of her pain after bilateral prefrontal lobotomy. However, two weeks postoperatively and several days after she had been told she could leave the hospital, a thrombosis of the left middle cerebral artery developed and the patient died. This diagnosis was proved at postmortem examination. The subcortical incisions in the brain were in good condition.

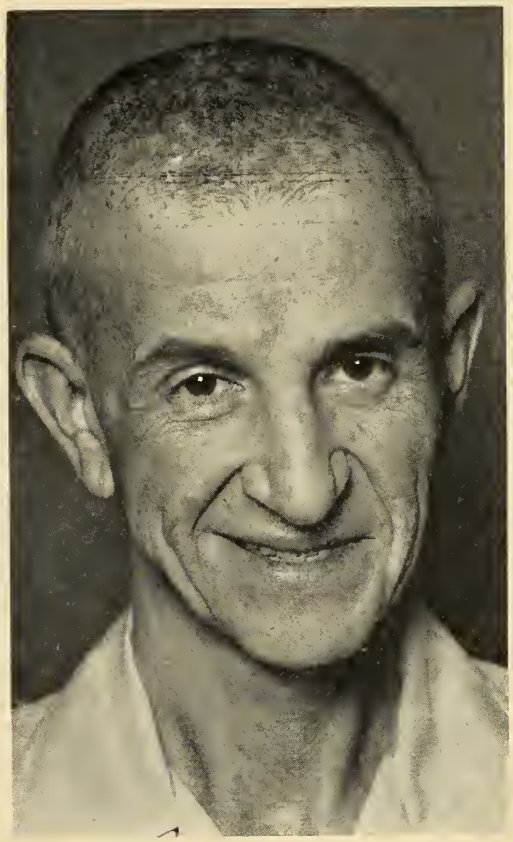

Fig. 3 (Case 4). Postoperative appearance. Remarkable change in facial expression has occurred after relief of the intractable pain. The lobotomy incisions are scarcely visible ten days after operation when this picture was made.

Summary and Conclusions

Nine patients suffering from intractable and uncontrollable pain in various parts of the body were subjected to bilateral prefrontal lobotomy. In four cases the pain was on an organic basis; in the remaining five cases, no organic cause could be found for the pain.

In six cases the relief of pain was remarkable and was considered satisfactory. The results in one patient with severe diabetes who succumbed to his illness cannot be adequately evaluated. One patient (Case 4) was completely relieved for a time, but he subsequently presented a behavior problem. The other patient was under observation in a mental hospital at this writing; the headache for which the operation had been performed was less troublesome, but he presented a problem in management.

THE EMERGENT CARE OF CRANIO-CEREBRAL INJURIES

WALLACE P. RITCHIE, M.D.
Saint Paul, Minnesota

FORTUNATELY, the majority of people who have suffered a head injury recover, regardless of the treatment instituted. On the other hand, there is a small group which will recover only by the evacuation of an intracranial clot, and another small group which will recover only because of the judicious use of a very few principles of general treatment.

Unfortunately, there is not yet a full and proper understanding of all the entities which go to make up the clinical picture of craniocerebral trauma. Our treatment in many instances is empirical. There has been, however, a great deal of experimental work performed in the last ten years which has aided in this proper understanding. Although the application of these experimental results is often difficult in the treatment of these cases, it will be well to mention briefly the more significant developments.

Experimental head injuries have given us a realization of the far-reaching effects of force transmitted to the brain. Gurdjian and Webster[4] show that certain changes take place. The most important of these are deformation of the skull (inbending and outbending), a sudden and momentary rise in intracranial pressure at the time of injury, mass movements of the brain, and injury to the brain by transmitted energy unassociated with increased intracranial pressure.

Denny-Brown and Russel[2] first showed the importance of acceleration and deceleration of the brain in the development of brain injury. Since then, there have been numerous studies showing the mechanism of coup and contrecoup damage, the effects of torsion and fractures of the skull. There is evidence that a fracture of the skull may have some positive value, in that some of the force is dispersed which might otherwise be transmitted to the brain.

The physiological basis of concussion is still under dispute. From a clinical point of view, the differentiation of pure concussion from actual brain damage would be of great value. Walker[9] gives evidence that pure cerebral concussion may be a sudden cerebral excitation (due to traumatic depolarization of the neuronal membrane) followed by a stage of depressed activity—so-called "extinction." This is similar to the state following epileptiform seizure, spontaneous or induced. He also states that unconsciousness lasting longer than fifteen to twenty minutes is probably associated with actual brain damage.

The role of brain edema is also, as yet, an unsettled question. From the evidence available, it is probable that patients do not die from brain edema alone. That there is a vasoparalysis following trauma, with slowing of the blood flow, associated with increased permeability of the vessels and a localized transudation of fluid is well demonstrated by Schenker and Evans.[7]

Windle[10] has shown that there was only a slight increase in the water content of the brain after concussion and that cellular changes were not due to this, but to the initial injury. Whether the increased pressure in the cranial cavity is due to actual edema or whether it be due to increased blood or spinal fluid content is not definitely known. At least one fact is quite well settled. Bragdon[1] has demonstrated that there is little justification for the routine use of dehydrating agents in head injuries, as the results are not only unpredictable but temporary. The consensus of present-day opinion supports him.

There is, however, some justification for the use of spinal fluid drainage in the reduction of increased intracranial pressure. This will be discussed at a later point.

When one considers that the brain shows great respiratory activity as evidenced by the low oxygen content of the venous blood, the importance of an adequate oxygen supply is self-evident. Although the oxygen content of the brain has been found unaltered after trauma except in contused areas, where it is low (Stone et al[8]), the brain cannot stand an oxygen deficit. "Whereas breathing of oxygen causes mild vasoconstriction, the addition of carbon monoxide to the inhaled mixture improves cerebral flow and postpones loss of consciousness" (Grennell and Hoff[3]).

The importance of glucose is evident, when one

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 7, 1948.

realizes that glucose is the substance of prime importance for cerebral oxidation. As there is no storage of glucose in the brain, its glucose needs must be met by the blood.

Diagnosis

If one realizes that aside from lacerations of the scalp and depressed fractures of the skull, the only entity which needs emergent care is a rapidly increasing intracranial hemorrhage, it becomes very evident that the recognition of this hemorrhage is the most important single feature in the early diagnosis of head injuries. Concussion, lacerations, contusions, and petechial hemorrhage of the brain, if present, are not amenable to any special treatment except supportive, and so-called edema may be somewhat affected by certain methods of treatment, but edema by itself is not an emergency.

Fortunately, the percentage of injuries which have surgical hematomas is small, but this is the group of cases in which there is not the slightest doubt that the proper surgical treatment will effect a favorable outcome.

Increased intracranial pressure is the one constant entity in intracranial hemorrhage. The recognition of increased intracranial pressure is therefore paramount.

There are four methods of determining the status of the pressure in the cranial vault:

(a) By observation of the patient.
(b) By observation of certain physiological signs.
(c) By spinal manometer readings.
(d) By eyeground examination.

Observation of the Patient.—There are few injuries in which repeated examinations are so necessary. An often quoted phrase is that "if they die within six or eight hours, nothing could have been accomplished anyway." This is a dangerous phrase, as many patients with extradural hemorrhages will die if not operated upon within the first six hours. In general, the symptoms of increasing pressure are increasing headache, occasional vomiting and increasing stupor. The last is the most important and the most difficult to evaluate. Frequently, patients are unconscious from the effects of concussion, contusion, or laceration of the brain. The depth of the stupor can be ascertained by the comparison of the response to a noxious stimulus (such as pressure behind the angle of the jaw, or supraorbital pressure at repeated intervals). A lessened response means a deeper grade of stupor. A lucid interval is by no means present in all cases of intracranial hemorrhage.

At the same time, evidence of localizing signs, such as paralysis, increased reflexes, positive Babinski signs, must be recognized.

Observation of Physiological Signs.—Normally, the intracranial pressure is slightly lower than the arterial pressure. If the intracranial pressure becomes greater than the arterial pressure, anemia of the brain develops. The anemic condition of the medulla stimulates the cardio-inhibitory center, which slows the heart beat, and at the same time the vasomotor center is stimulated so that there is a general vasoconstriction which raises the blood pressure, and thus cerebral circulation is re-established. Every case of rapidly increasing pressure will at some time show a high blood pressure and slow pulse unless, of course, there is shocking hemorrhage elsewhere. After a critical point, when the pressure in the skull is too great for this compensatory mechanism, there will be a fall in blood pressure and elevation of pulse with respiratory paralysis. Not infrequently, the stage of compensation may have occurred before examination by the physician. Blood pressure and pulse recordings should be made every fifteen to twenty minutes.

Spinal Manometer Readings.—Spinal puncture in the treatment of head injuries is a much discussed problem. There is no question but that intracranial pressure can be reduced temporarily by this means, but if an intracerebral clot is present, what is the use of drainage which will not avert the hemorrhage and may only cover up the important signs which lead us to the diagnosis? In the acute phase of the injury, we are interested only in determining whether there is a hematoma that must be evacuated. As a rule, the observation of the state of consciousness of the patient and the observation of the blood pressure and pulse will give us ample evidence in the acute extradural or subdural hemorrhage. Frequently, however, a patient fails to respond in twenty-four hours, the pulse and pressure and state of consciousness has varied little, and the

patient may be developing a slowly increasing clot or edema. It is in these instances that a spinal puncture is performed as a diagnostic and not a therapeutic measure. One should not do a spinal puncture without measuring the pressure by manometive means.

Eyeground Examination.—This last method of determining increased intracranial pressure is of least importance in the treatment of acute injuries. In the first place, it is several days before it appears, and it takes a practiced eye to determine early changes. However, when it is present, it is of great importance, and therefore frequent examinations should be made.

X-ray in the diagnosis is only important if a depressed fracture is suspected, or if an exploration for hemorrhage is contemplated. This latter is mentioned, because occasionally in cases with an extradural hemorrhage the bleeding occurs at the point where the fracture line crosses a main branch of the middle meningeal artery, and a trephine over that point may be all that is necessary for evacuating the clot, and controlling the bleeding point.

Encephalography and ventriculography are rarely, if ever, used in the diagnosis of acute injuries. It has a definite place, however, in the diagnosis of the late sequelae, such as late subdural hematoma, cysts, and brain atrophy.

Electro-encephalograms are not as yet practical; however, they will undoubtedly prove of value in that the persistence of abnormal findings may prognosticate future trouble.[5]

Treatment

If one could be assured that no surgical hematoma were present, the emergency care of trauma to the head in the majority of instances would be a matter of supportive treatment.

General Supportive Measures.—The relative importance of the cranial injury to other injuries that may be present is often difficult to determine. There is no condition more emergent than a rapidly increasing intracranial hemorrhage, except a shocking hemorrhage elsewhere or possibly a sucking wound of the chest. After the general state of the patient is determined and a plan of action for care of fractures, lacerations, and internal injuries is made, supportive and watchful care is carried out, with special attention to changes in blood pressure, pulse, depth of stupor, and neurological changes.

An adequate airway is of paramount importance, as the effects of an oxygen deficit in the brain are far reaching. The removal of orotracheal and bronchial secretions in a patient who has lost his cough reflex is vitally important. An intratracheal tube or even a tracheotomy may be in order in selected patients. A strict order for nothing by mouth until the patient is well awake will lessen the chance of the all too frequent aspiration pneumonia.

Adequate nutrition is essential. So much attention has been paid to dehydrating agents that harm is done by overzealous efforts in this regard. As a rule, little attention is given to the administration of fluids in the first twenty-four hours. After this, at least 2,000 c.c. of fluid is administered, and if the patient fails to respond by seventy-two hours, sufficient caloric intake and fluid, either by gastric tube or parenterally, is given to assure adequate nutrition.

Care of Individual Entities.—

(1) Scalp wounds.—The only comment necessary is that an infected scalp wound is a serious defeat for the attending surgeon.

(2) Depressed fracture.—As a rule all depressed fractures should be elevated. Except where the dura has been punctured the elevation of a depressed fracture is not an emergent procedure.

(3) Intracranial hemorrhage.—A trephine over the point where the fracture line crosses a large branch of the middle meningeal artery on the suspected side may reveal not only the hemorrhage but the point of bleeding. The clot is sucked away, and a clip or silk suture closes the artery. If the bleeding persists from another point, as much bone may be rongeured away as necessary. Cranial defects can always be repaired.

If the clot is subdural, it is sucked away and the area washed with warm saline until bleeding is controlled.

If there is doubt in regard to the control of bleeding, a drain can be inserted, the wound closed, and then the patient can be transported or neurosurgical consultation be obtained.

The rapidity of onset of extradural hemorrhages and acute subdural hemorrhages often make neurosurgical consultation impossible and in

these instances a life-saving trephine must be made by the general surgeon of the community.

The late subdural hematoma does not come in the province of emergency surgery, and inasmuch as it often requires extensive craniotomies, it should be taken care of by one specially trained.

Brain Swelling—Edema.—That there is a moderate increase in intracranial pressure after trauma is evident. Whether this is due to actual tissue edema or increased cerebrospinal fluid or blood is still debatable, as evidenced by those schools which advocate extreme dehydration, no dehydration, frequent spinal punctures, and no spinal punctures.

It is well to remember that patients do not die from this cause alone.

It has been shown that there are no hypertonic solutions which give more than a temporary decrease of intracranial pressure.

Munro[6] has been the persistent advocate of repeated spinal punctures. It is of value if one is assured that there is no surgical hematoma whose presence will be masked by the repeated lowering of spinal fluid pressure. Its use should be limited to the patient who has not shown any of the physiological signs of intracranial pressure or localizing signs of a hematoma and who has failed to respond in the first twenty-four hours, and in whom the spinal fluid pressure is elevated. A spinal puncture every six to twelve hours may be indicated. Enough fluid is removed to bring the pressure to normal.

The danger of masking a subdural hematoma by this method cannot be overestimated. If the pressure remains over the upper limits of normal (usually over 200) after repeated punctures for three or four days and the patient fails to arouse from his stupor, multiple trephines must seriously be considered.

Posttraumatic Care

The care of the posttraumatic sequelae is not a part of this program. Suffice it to say that early ambulation and minimizing the effects of concussion, fracture of the skull, vertigo and headache will lessen the number of those cases which are so difficult to treat—the so-called posttraumatic neuroses.

Summary

The emergent care of head injuries is, as a rule, supportive, except when a rapidly increasing intracranial hemorrhage is present. The early diagnosis of this hemorrhage and its evacuation is by far the most important active role that the physician is called upon to play in these cases.

PREFRONTAL LOBOTOMY

(Continued from Page 153)

It is our opinion that the operation of prefrontal lobotomy is justified and indicated in certain carefully selected patients who are suffering from intractable pain, whether of organic or functional type, when less radical measures fail to give relief.

TOXEMIAS OF PREGNANCY

WILLIAM B. STROMME, M.D., F.A.C.S.
Minneapolis, Minnesota

THE TOXEMIAS of pregnancy have become one of the most important matters we handle in practicing obstetrics. As a group they occur in about 10 per cent of all pregnancies and are a major cause of maternal as well as fetal disaster. As a preface for this survey it may be well to discuss some pertinent statistics.

According to the latest United States Bureau of Census report, the toxemias constitute today some 26 per cent of all maternal deaths. In our own state we are doing better, not only on a total maternal mortality figure, but on the relative percentage of toxemias as well. And, more important, as the years go by, we are bettering ourselves. Remarkable strides have been made in Minnesota in bringing the maternal mortality rate of 5.8/1000 in 1924 to but 0.6/1000 in 1947. Obviously much of this gain, or increase salvage rate, has been due to the discovery and use of sulfonamides and antibiotics in combating puerperal infection, and to the more generous use of blood and plasma in the treatment of hemorrhage.

Our interest in this presentation centers around the toxemias: what we are doing and what can be done. Again from a statistical point of view, the percentage component of maternal deaths due to toxemia has, with the exception only of the last few years, shown little reduction from the figure of 22 per cent in 1922. Total deaths per year from toxemias have shown a steady decline. In a recent twelve-month survey by our State Board of Health, fifteen cases of maternal death from toxemia were carefully studied. Some interesting facts were disclosed. All but two of these deaths were preventable, either on the part of the physician, the patient, or both. Inadequate prenatal care, radical and unsuited methods of delivery, improper anesthesia, and faulty postpartum care were found contributing factors.

Considerable advances have been made even since 1942. In 1946 there were 67,303 live births in the state with sixty-nine deaths, giving a maternal mortality rate of 1/1000. In 1947 there were 75,467 deliveries with fewer deaths (only forty-seven), giving an extremely low rate of 0.6/1000 live births. Three toxemia deaths occurred in 1946 and only two deaths were attributed to this cause last year. In Renville County in 1946 there were eighty-nine deliveries with no maternal deaths, and in 1947 there were sixty-seven deliveries with no deaths.

From the foregoing it might almost seem that a discussion of toxemias is unneeded, particularly in Renville County. However, in view of the general importance of the disease group, I should like to present a brief discussion of the various toxemias, emphasizing in each the diagnosis and practical methods of treatment.

A uniform classification of the toxemias has been established by the American Committee on Maternal Health. It is the one we employ and probably the one which is most familiar:

Vomiting of Pregnancy (and Pernicious Vomiting)
Acute Yellow Atrophy
Hypertensive Disease
Renal Disease
Mild Pre-eclampsia
Severe Pre-eclampsia
Eclampsia
(Unclassified)
(Superimposed toxemias)

The occurrence of toxemias is unquestionably lessening. Ten years ago at the New York Lying-In Hospital it was approximately 10 per cent. Last year that figure was 5.43 per cent. Logical explanation, of course, can be given in improved prenatal care and diet; probably other, as yet unknown, factors also have contributed. The percentage of toxemias last year at the New York Lying-In Hospital was as follows:

	Per Cent
Pernicious Vomiting	0.0
Acute Yellow Atrophy	0.0
Hypertensive Disease	30.0
Renal Disease	2.0
Mild Pre-eclampsia	45.0
Severe Pre-eclampsia	20.0
Eclampsia	2.0
Unclassified	1.0

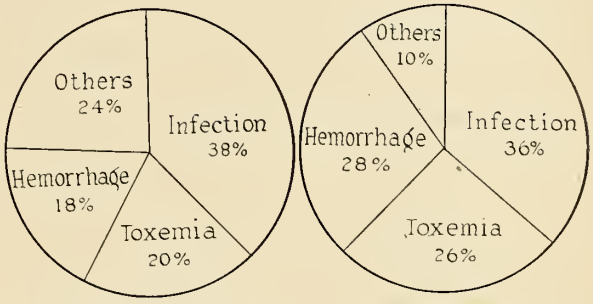
During the past decade there has been little change in this picture excepting that more of the formerly termed "nephritic toxemias" are now

Read before the Renville County Medical Society meeting, March 9, 1948.

classified under "mild pre-eclampsia"; and that eclampsia has become less common, due evidently to better care of the pre-eclamptic patient.

Vomiting of Pregnancy

So-called "morning sickness" (and as often it is "afternoon sickness") occurs in at least 50 per cent of all pregnancies. Its development, when on a toxic basis, is limited almost entirely to the first trimester. It is the garden variety and nearly always benign. As such it should be distinguished from the rare but often malignant type, properly termed "pernicious vomiting of pregnancy" or "hyperemesis gravidarum."



Three etiologic factors have been taught for the past forty years: (1) reflex; (2) neurotic; and (3) toxemia. Present-day concepts largely exclude the first of this list. There is still diversity of opinion, however, as to the importance of the second. While Stander, an authority in this field, believed that practically all are on a toxic basis, many of us practicing obstetrics believe the neurotic factor to be equally important. Disturbed metabolic processes and possibly also hormonal upsets would seem to play a part.

The well known symptoms are those of vomiting and its sequelae: dehydration, starvation, lassitude, polyneuritis and others. In pernicious vomiting these symptoms become very pronounced and may progress—at times most rapidly—to: coffee ground vomitus from gastric hemorrhage, marked dehydration, jaundice, coma, and even death.

Diagnosis of vomiting of pregnancy usually presents no problem, since it is largely confined to the first three months and nearly always responds to proper management. It is important, however, to differentiate this condition from other causes of vomiting in pregnancy, for example: gastric irritation from pressure of the gravid uterus, peptic ulcer, and diaphragmatic hernia.

Severe vomiting may even lead to death and consequently it is important to watch for evidence of the serious symptoms enumerated. A study of the eyegrounds in the pernicious vomiter shows at times variable degrees of hemorrhage. The blood chemistries may be altered with pulse and temperature elevation. Determination of urine acetone by the simple sodium nitroprusside test will point the need for close observation of all such patients with positive test. I personally find it helpful in deciding which patients are in need of hospitalization.

Recommended treatment is as follows: For those with mild symptoms, first eliminate fatty and highly seasoned foods, coffee, raw fruits, raw vegetables, and milk. I further recommend five rather than three meals a day; or snacks between meals, preferably crackers, toast or cookies.

U. S. Registration Area Minnesota

Primary Causes of Maternal Death

A mild sedative such as phenobarbital is usually prescribed. Along with such advice it is well to encourage the patient and reassure her that the condition is self-limited and will respond to treatment.

Where the condition is more than bothersome, the administration of large doses of thiamine and pyridoxine has been of decided help to many, but unfortunately not all, patients. Intravenous and intramuscular injection is definitely superior to the oral route. We recommend at least 50 mg. of each per injection, and do not hesitate repeating injections every few days if there is beneficial response. Several oral preparations are available, though vitamin potency is comparatively low. Occasionally the addition of parenteral ascorbic acid and liver extract will aid in response.

In those requiring hospitalization the following routine is suggested:

Until vomiting ceases:

Nothing by mouth for an additional twelve hours after vomiting ceases. Three thousand c.c. of 5 or 10 per cent glucose given parenterally each day, 2,000 c.c. of which to be glucose in saline.
Parenteral thiamine, pyridoxine and ascorbic acid.
Complete isolation from all visitors and relatives; single room; and strict bed rest.
Reassurance from the doctor and nurse.

After vomiting ceases:

1st day: Dry and frequent feedings consisting of toast, baked potatoes, crackers, etc.
Parenteral fluids.

2nd day: Same dry diet of five meals between which patient may have small amounts of tea and carbonated beverages.
3rd day: Full diet.
May be allowed up.

The unusually stubborn case will require more effective measures, including gastric lavage and subcutaneous fluids with long needles. For that rare case where serious pernicious vomiting occurs, it may be necessary to abort the patient to save her life. At the New York Lying-In Hospital in the past fourteen years only six such abortions were required of 59,000 obstetric patients seen.

Acute Yellow Atrophy

This rare toxemia is not exclusively one of pregnancy, or of women. It is characterized by jaundice, drowsiness, headache, vomiting, diarrhea, delirium or coma. It may occur at any time during pregnancy, and leads rapidly to death in many instances (30 per cent mortality). The picture is one of severe liver damage both from clinical and pathological viewpoints.

Etiology of the toxemia in some cases can be established on the basis of liver poisoning. In others no specific factor is known although there may be contributing circumstances such as syphilis, chronic passive congestion, and cirrhosis of the liver.

The disease is usually sudden in onset, quickly presenting jaundice, lethargy, markedly toxic symptoms and convulsions. At first the liver may be palpable and tender, then gradually shrinks in size. Albuminuria is present. Diagnosis is made on this clinical picture, history of poisoning, a high icteric index and a positive Van den Bergh test. It may be confused with toxic vomiting and eclampsia.

Treatment should be directed in a general way to combat the toxemia and specifically to support and aid the liver. The patient should be hospitalized and should receive 500 c.c. of 20 per cent glucose intravenously four times a day. Recent advances indicate the wisdom of administering intravenous amino acids to fortify the liver, and molar lactate solution in 500 c.c. amounts as needed to maintain acid-base equilibrium.

Hypertensive Disease

Hypertensive cardiovascular disease is not a true toxemia, but is so classified because it is often first recognized in pregnancy and may be confused with the pre-eclamptic, eclamptic toxemias, as well as with renal disease. According to Volhardt and Fahr two groups are found, benign and malignant. More recent workers have divided the condition into four classes. From a practical standpoint, however, it is important for us in the handling of an individual case, or cases, to be able to differentiate the non-progressive benign, from the progressive or malignant type.

A discussion of etiology as well as experimental work on this subject alone would be a major enterprise and is without the scope of this paper. Briefly, however, it may be said that the popular theory of renal ischemia liberating renin as an initiating factor of hypertension, is open to serious doubt. According to Goldring and Chassis, the fundamental factor is an increase in total effective peripheral resistance due at first to reversible arteriolar spasm; later the arteriolar changes become permanent. The renal ischemia noted in these patients appears, to these authors, to be the sequelae and not the cause of the hypertension.

Attention should be given to a careful recent study by Chesley and associates at the Margaret Hague Hospital in Jersey City. They found, and quite contrary to the generally stated opinion, that repeated pregnancies in hypertensive patients do not increase their expected annual death rate (which incidentally is unusually high anyway, i.e., six times the expected death rate of normal women!) They also discovered that where pre-eclampsia is superimposed on the hypertensive patient, the maternal death rate increases the patient's risk tenfold.

Hypertensive disease may, of course, precede the pregnancy or first become manifest during pregnancy. A history of previous hypertension is often elicited and is very helpful in establishing the diagnosis. As a so-called toxemia, it is not limited to any one period of gestation, but will likely be present by the second if not the first trimester. Its symptoms are well known. Blood pressure values are often in the neighborhood of 150-160/90-100; but may be considerably higher. There is little or no accompanying edema and urine tests are clear for protein. If further diagnostic work is required, renal function tests will show normal values, except in the far advanced cases with secondary renal involvement. Blood chemistries will likewise be normal. In this toxemia considerable help will be

found in ophthalmoscopic eyeground studies, where even early hypertension will evidence some arteriolar spasm. Later in the disease, permanent vascular changes are seen. Hallum reported that, "The degree of eyeground changes more closely follows the severity of hypertension and consequently the toxemia than any other sign."

Treatment is largely that of medical management of the non-pregnant hypertensive patient. The general tried and true measures are the best, namely; rest, sedation, restriction of activity, and a quiet well regulated life. Thiocyanate treatment in pregnancy has been without much success. Surgical procedures are not advisable during pregnancy, but may be considered postpartum.

Concerning the problem of obstetric management of the hypertensive patient, she must be observed more frequently and more critically throughout pregnancy. At times hospitalized rest may be required. Sedation should be generously given during labor, yet not to retard or prolong it. Delivery by forceps is desirable as soon as full dilatation of the cervix is reached to prevent the extra effort of the second stage. Anesthetic of choice is local pudendal block type.

One may be faced with a decision as to interruption of the pregnancy. Hypertensive disease alone is not enough. However, if there is evidence indicative of severe hypertension then one may justifiably recommend termination. Certainly with impending pre-eclampsia such indication is undisputed.

Renal Disease

Formerly termed "nephritic toxemia," it is in many respects like the hypertensive disease and not really toxemia at all. Renal disease complicating pregnancy is commonly grouped herein because of many similarities with the "true toxemias." It is a heterogenous composite of three divisions: (1) glomerulonephritis; (2) renal arteriolosclerosis, and (3) tubular nephrosis. The background of each of these is different and is well known. From a practical standpoint, the majority of obstetric patients with renal disease fall into the arteriolosclerotic or nephrosclerotic type. As with hypertensive disease, history of previous renal disease may help to point to the diagnosis. It may occur in either the first, second, or third trimester. It usually begins insidiously with albuminaria, not much else. The urine will often contain casts as well. Sooner or later, hypertension will be present. Edema may become marked, particularly with the nephrotic types. Symptoms are those of lassitude, headache, dizziness and visual disturbances. When the disease is mild the patient may not present any symptoms, but the one important lead is albuminuria. And this, incidentally, should always be differentiated from that of pyeloureteritis by microscopic study. In the severe types, urine output falls and with it there is retention of nitrogenous products and symptoms of uremia.

Where the story and office findings are not conclusive, it is important in view of the bad prognosis to hospitalize the patient for renal function tests. While inulin and diodrast clearance tests are more sensitive, the old standbys, concentration and dilution, P.S.P. tests, blood urea nitrogen and blood uric acid, will prove reliable in differentiating this condition from the so-called "true toxemias." Of further aid is the use of the ophthalmoscope, finding in established cases of renal disease the retinal hemorrhages and old areas of fibrosis and scar.

The prognosis of renal disease is bad; both the maternal mortality rate and fetal mortality rate are high. There may be intrauterine fetal death or premature delivery. Explanation has been given in the frequent large placental "infarcts" supposedly restricting nutrition and oxygen to the fetus. However, other unknown toxic factors seemingly play a role.

Treatment is in the main the medical treatment of renal disease *per se,* with restriction of fluids and salt plus the use of mercurial diuretics in the severely ill patient. For those in whom the disease is not far advanced and without uremia, there is a trend today toward a moderate fluid intake and no restriction of protein with but moderate limitation of salt. As in the treatment of the hypertensive patient, of equal importance is the well managed orderly life.

From the obstetrician's consideration, since the prognosis is poor for both mother and child, one should not hesitate in terminating the pregnancy at any time in the more serious chronic nephritic patient. Where allowed to continue, obstetric management is essentially the same as stated under hypertensive disease. Under certain circumstances, cesarean section before term when the fetus is viable may be performed in the interest of the baby in view of the high intrauterine

death rate. Postpartum sterilization should be wisely considered.

Mild Pre-Eclampsia

This toxemia, formerly called "low reserve kidney," is the mildest form of the true toxemias and the most common. It is characterized by a mild rise in blood pressure up to 160/100, slight albuminuria, slight edema, and abnormal gain in weight. The toxemia is limited to the third trimester. Its symptoms are correspondingly mild or absent. Its beginning is typically mild with perhaps a trace of albumin and a blood pressure rise often not even beyond the normal limit of 140/90. There may or may not be significant weight increase and edema. One week later these same findings will again be present and may be no different—but more probably all will be a little more prominent. There is usually no antecedent history of toxemia and this is most often the first pregnancy. Also, in contrast with the hypertensive toxemia, the patient is more likely a young woman of late teens or early twenties. If further diagnostic measures are needed, the blood chemistries as well as renal function tests and eyeground findings will all be found within normal limits.

If the symptoms are mild and present for the first time, it is generally safe to permit the patient to follow out a toxemia regime at home, and to see her again in one week. Such suggested management is as follows:

Rest. No outside activity, no walks, no trips to the store, no company. One hour bed rest in the morning and one or two hours bed rest in the afternoon.

Sedation. Phenobarbital, one-half grain, twice or three times a day. Restriction of salt, limiting to one-half the usual amount. Limitation of fluids if there is edema to one and one-half quarts a day. Saline cathartic, for example Epsom Salts, one tablespoon in one-half glass water before breakfast once or twice a week.

The use of the low protein diet is gradually being abandoned in favor of a normal or even high protein intake. There is more logic in the latter and no adverse effect on the toxemia. The patient is advised to call in at any time if she has: headaches, epigastric pain, spots before the eyes, or increased swelling. Where mild pre-eclampsia does not respond to these measures, strict bed rest in a hospital and stringent adherence to these rules should be carried out. Regarding the prognosis, it may be reasonable to expect at least 40 to 50 per cent improvement by such management. Fortunately many patients exhibiting pre-eclampsia will go into labor early or following a temporary improvement in status.

Severe Pre-eclampsia

This disease is serious in that it is so frequently the percursor of eclampsia. It is usually of sudden onset, occasionally being preceded by mild pre-eclampsia. Only infrequently will there be history of previous toxemia. It is found in the third trimester, often in primigravid young adult women. It is characterized by high blood pressure, around 180-200/110-130, with a correspondingly high amount of albumin in the urine. Specimens may contain as much as 3 to 4 plus, i.e. up to 10 Gm. per liter, of albumin; edema may be marked or absent. The patient need have no complaints, but usually has a peculiar "sick feeling," with headaches or epigastric pain and may have visual disturbances. Urine output is diminished, but there is no increase of blood urea nitrogen; only the blood uric acid rises. Eyeground studies only occasionally show spasm and retinal edema. Kidney function tests are usually unaltered. Such a story and record serve to indicate the diagnosis, while follow-up studies and postpartum response should confirm it.

The immediate prognosis for the mother is unquestionably hazardous in that eclampsia often follows. The fetal mortality rate in severe pre-eclampsia alone is 20 per cent. The ultimate prognosis for the mother finds approximately 20 per cent having recurrences of toxemia in subsequent pregnancies.

Proper and prompt treatment of mild pre-eclampsia and good prenatal care, good health and diet are important in prevention of severe pre-eclampsia. Once the latter exists, hospital care is mandatory. The patient should be placed in a single dark room and disturbance kept at a minimum. Sedation should be started with morphine, grains one-fourth, and repeated in four hours. This should be supplemented with chloral hydrate or barbiturate every six hours. By giving 500 c.c. of 20 per cent glucose in water intravenously four times a day, diuresis will be stimulated. Acidosis if present can be combated with intravenous molar lactate solution in 500 c.c. amounts. Oxygen should be available as well as a tongue blade mouth gag in the event of convul-

sions. Diet should be soft, low in salt, with oral fluids restricted to 1,500 c.c. a day, if edema is present.

If response is not forthcoming in forty-eight hours under such a regime, non-traumatic delivery is advised. Usually this means Cesarean section under local anesthesia. However, in some instances, if the patient be a multipara and at term with a partially dilated and effaced cervix, medical induction with rupture of membranes may be better suited. Delivery then, as in spontaneously initiated labor, should be by forceps at full dilatation of the cervix. The preferred choice is local anesthetic, inasmuch as all inhalation gases may be further toxic to the liver.

It must be remembered that not infrequently intrauterine death of the fetus will occur—before, during, or after the start of such treatment. Often this development is followed by spontaneous improvement in the toxemia.

Eclampsia

This dread toxemia is gradually becoming a rare entity. About 25 per cent of cases occur before labor, 50 per cent during labor, and 25 per cent postpartum. Some of the latter group we have recently shown to occur as late as the eighth postpartum day. Essentially eclampsia is the same as severe pre-eclampsia with superimposed convulsions. The background is the same as well as the characteristics and diagnostic features.

The etiology of eclampsia still remains obscure. It is the disease of many theories and there is little to be gained by a detailed discussion of them. However, some important facts and recent developments which seem on the verge of finally explaining the disease process, merit attention. They are in brief outline:

1. Primiparity, twins, and hydramnios definitely predispose to pre-eclampsia and eclampsia.

2. Eclampsia is higher in undernourished, "ill fed, ill clothed, and ill housed."

3. Renal ischemia does not play a role in pre-eclampsia or eclampsia. And renal blood flow is unchanged in the true toxemias.

4. Dexter and Weiss attribute the cause of the toxemia to "something within the placenta"; and not to the fetus or the mother.

5. Smith and Smith state on the basis of preliminary studies, that pre-eclampsia and eclampsia are due to a menstrual-like toxin present in the blood of such patients. The toxin is derived presumably from the placenta or is of decidual origin; it does not occur in the normal parturient patient.

The prognosis of eclampsia properly treated today is now well under a 5 per cent maternal mortality. The fetal mortality rate, however, is still high, 40-50 per cent. Eclampsia will recur in subsequent pregnancies in about 4 per cent of cases; but other toxemias will occur in 35 per cent. In general, the immediate prognosis is worse in antepartum and intrapartum eclampsia, in the presence of prolonged coma, a high pulse rate, a high blood pressure, high fever, more than ten convulsions, more than ten grams of albumin per liter of urine, and absence of edema.

In the main, good treatment of pre-eclampsia is good prevention of eclampsia. However, an occasional case will fulminate so rapidly through pre-eclampsia to eclampsia that little can be done in the way of prophylaxis. Unquestionably the best treatment of eclampsia is a conservative one. Stroganoff management, introduced in 1924, has already been detailed. It should be modified as mentioned with addition of hypertonic glucose every six hours plus molar lactate solution to combat acidosis. Veratrum veride has again shown some popularity although it has been combined with other sedative drugs and its beneficial action disputed.

Usually, labor supervenes in the antepartum patient; but on selected occasions, induction of labor and/or operative delivery, including cesarean section, may be necessitated.

COMMON ERRORS IN RH TESTING

JOSEPH W. GOLDSMITH, M.D., F.A.C.S.
Saint Paul, Minnesota
and
JOHN L. McKELVEY, M.D., C.M.
Minneapolis, Minnesota

ERRORS in Rh testing have led to many instances of severe transfusion reactions and even to fatalities. Equally as tragic is the sensitization of Rh-negative girls and women in the child-bearing age by transfusions because of erroneous classification with respect to the Rh factor. Such sensitization may jeopardize future pregnancies, giving rise to congenital hemolytic disease of the newborn (erythroblastosis fetalis) and may even destroy the woman's chance to have one normal infant (cf. Case 1). Since such mistakes are largely preventable, it is imperative that the causes be discovered and eliminated where possible. It is our purpose to explain some of the more common errors and to suggest means to eliminate them.

Faulty technique, the use of serum of low antibody content, the use of old serum or serum that has not been properly handled, and attempting to test old blood specimens are some of the major factors responsible for inaccuracy in Rh testing, i.e., the determination of Rh status.

It is of utmost importance that the proper type of antiserum be used for the particular method employed. When testing by the slide method of Diamond and Abelson,[1] only antisera containing blocking (univalent) antibodies can be used and all crystalloids must be eliminated from the system. The vial of testing material should state: "For the Slide Test Technique." Any other sera should not be used for this test. For tube testing, antisera containing either blocking antibodies or agglutinins (bivalent) antibodies or both, may be used. Regardless of the method employed, the proper conditions of temperature and time must be observed for that particular method. For example, when performing Rh tests by the tube technique, the tubes must be incubated at 37° C. for one hour before they are read. Thereafter, they may be read with or without centrifugation.

A frequent source of error has been the antiserum itself. Testing sera of animal origin will react with the red blood cells of all newborn infants to give a positive test regardless of Rh status. Many such sera will also give results on other erythrocytes that cannot be constantly reproduced. Hence human, rather than animal sera should be used. Moreover, various lots of antisera even from the same source vary in speed of reaction, specificity and degree of agglutination produced. Much of this is determined by the antibody titer. Antisera with a low titer may fail to agglutinate cells containing agglutinogens which are "weak" or incomplete. Therefore, it is essential that each new lot of testing material be checked against known Rh-positive cells, preferably of several Rh types. The National Institute of Health has established a titer of 32 as a minimum acceptable standard.

Antisera will lose their effectiveness rapidly at room temperature and more slowly if refrigerated. Hence, they should be checked from time to time against known cells and replaced if agglutination is weak or delayed. This check will become routine if known Rh-positive and Rh-negative cells are included as controls in each series of unknown cells tested.

Samples of blood to be tested lose their ability to react even with potent antisera when hemolysis occurs. Hemolysis proceeds rapidly at room temperatures and more slowly at icebox temperature. Fresh specimens are preferable, but when they cannot be tested immediately, they should be refrigerated and checked as soon as possible. Perfectly dry syringes, needles and receptacles should be used. Chemical anticoagulants should be avoided.

Occasionally errors have resulted from rouleaux formation. In some instances, it may be extremely difficult to distinguish between rouleaux and true agglutination. Frequently, the addition of a drop of the appropriate diluent will help in this differentiation since it will break up rouleaux aggregates but will not affect agglutinates.

In the slide technique, two additional sources of error may arise. False positive reactions may result from drying and false negative results may occur when the suspension of test cells used is

From the Department of Obstetrics and Gynecology, University of Minnesota Medical School.
Read at the semiannual meeting of the Minnesota Society of Obstetrics and Gynecology, November 7, 1947.

not concentrated enough. To prevent incorrect results from drying, the test should be read at the end of one minute, and if an unusual amount of drying has occurred at this time, the test should be repeated. False negative reactions may be prevented by using cell suspensions which are approximately of 35 to 50 per cent concentration.

It is not within the scope of this presentation to include the more technical aspects of this problem but several instances may serve to stress the necessity for the elimination of all possible errors.

Case Reports

Case 1.—Mrs. F. W., aged twenty-six, was first hospitalized in 1942 with severe abdominal pain, vaginal bleeding and symptoms of shock after an amenorrhea of six weeks. She had never previously been pregnant. A diagnosis of a ruptured ectopic pregnancy was made and confirmed at laparotomy. She was given 1,000 c.c. of type-specific Rh-positive blood and made an uneventful recovery. She again became pregnant in 1945 and delivered a severely edematous, erythroblastotic infant at term. The infant was stillborn. Check of her Rh status disclosed that she was Rh negative instead of Rh positive as had been reported previously. The cause of the erroneous determination could not be discovered. The maternal serum contained Rh antibodies in a titer of 1:512 in saline and of 1:1024 in bovine albumin. She again became pregnant in 1946 and again delivered an edematous stillborn infant near term.

In this instance, despite the fact that the husband is Rh positive, sensitization was most likely produced by the large transfusion of Rh-positive blood in 1942, at the time of her operation, as the result of faulty Rh determination. Her prospects for having a child of her own in the future are not good.

Case 2.—Blood from Mrs. K. J., twenty-two years of age, was sent to our laboratory for determination of Rh status because two other sources had reported contradictory results. A test made in the physician's office had shown the patient to be Rh negative whereas she had been classified previously as Rh positive by a hospital laboratory. When the patient was found to be Rh positive, investigation disclosed that the testing serum used in the doctor's office was more than six months old because only occasional tests were done there. Even though it had been refrigerated during this time, an antibody titration revealed a residual titer of 1:2, but only weak agglutination of known Rh-positive cells was produced even with the undiluted serum.

Case 3.—Mrs. E. M., aged twenty-eight, had been tested for the Rh factor during her prenatal period and was said to be Rh positive. Two previous pregnancies and deliveries had not been unusual in any respect, and the children were alive and well. After an uneventful antepartum course, she spontaneously delivered a normal 8-pound male infant. The placenta was retained and had to be removed manually. This procedure was accompanied by a blood loss estimated to be 450 c.c. A transfusion was ordered, and in rechecking the patient's Rh status, she was found to be Rh negative. Investigation disclosed that the laboratory which had performed the original test routinely used anti-Rh_0', or so-called 87 per cent serum. When the patient's cells were typed, she was found to belong to type Rh'. Although the incidence of this type is only 1 per cent among Caucasians,[3] it is possible for such individuals to be sensitized by either the Rh_0 or Rh" antigens or both. Stilwell[2] has recently pointed out that persons who have blood which is classified in any of the groups, Rh negative, Rh', Rh" and Rh'Rh" should all be considered as Rh negative when they are to be recipients of blood or in obstetrical problems concerned with the Rh factor. However, blood classified as type Rh', Rh" or Rh'Rh" must be considered as Rh positive when it is to be used as donor blood. Had the original testing been accepted as correct and Rh-positive blood been given to this patient, it might have sensitized her to the Rh factor. This in turn might have led to later transfusion reactions or to erythroblastosis fetalis in future pregnancies

Comment

Unfortunately, most laboratory reports are accepted as correct and are seldom questioned. To eliminate this, it would be advisable to check all Rh tests by several methods or have the tests performed by different laboratories. In this way, sources of error may be discovered and eliminated before tragedy ensues.

Summary

Several of the more common sources of error in Rh testing have been emphasized and means suggested for eliminating them. Illustrative cases are reported demonstrating the necessity for eradication of all possible errors.

A NEW AND SATISFACTORY OPERATION FOR PROCIDENTIA

ARTHUR E. BENJAMIN, M.D.
Minneapolis, Minnesota

UTERINE prolapse has plagued the lives of many women in the past, and today is still one of their major complaints. The laity has considered it a natural result of childbearing and advancing years, and the fact that the prescribed remedies are frequently unsatisfactory has led some patients to refuse treatment.

The treatment of uterine prolapse is still a controversial subject among gynecologists.[4] Certain practitioners, mindful of the failures in this field of surgery, are loath to advise or perform a surgical operation, but employ some make-shift support or pessary, endeavoring to minimize the discomfort of the patient. The many different operations that have been devised for uterine prolapse indicate that the profession has not yet arrived at the solution of this problem.

Physicians who would give advice in this field should thoroughly understand what forces govern and maintain the uterus in its normal relationship to other pelvic and abdominal organs. The initial stages of a prolapse are often unrecognized. Usually a woman with a procidentia has had the supportive structures damaged during childbirth, but there may be a complete prolapse in the nullipara.

In this paper I wish to emphasize and especially consider prolapse of the uterus of the third degree, or procidentia, realizing, however, that it is inseparable from the consideration of prolapse of the first or second degree.

Normal Supports of the Uterus

The structures and forces which maintain the uterus in its normal position are as follows:

1. The uterosacral ligaments prevent the cervical portion of the uterus from dropping and hold it backward.
2. The round ligaments hold the fundus forward. The uterosacral ligaments and round ligaments together hold the uterus at right angles to the vagina.
3. The broad or cardinal ligaments maintain the uterus at its normal level.
4. The pubo-vesico-cervical fascia and
5. The recto-vaginal fascia encase and hold up the vagina, as well as help to support the bladder and rectum.
6. The perineal and levator ani muscles form the floor upon which the fascia surrounding the vagina rests.
7. The intra-abdominal pressure, when the uterus is in normal position, helps to maintain the uterus at right angles to the vagina.

Causes of Prolapse

It is evident that any of the following conditions may favor a prolapse:

1. Congenital weakness of the normal supports.
2. Certain occupations that require women to be on their feet much of the time.
3. Bad postural habits, causing visceroptosis.
4. Tumors within the abdomen or growths pressing upon the uterus.
5. A subinvoluted uterus or one heavy from inflammation.
6. Gastrointestinal disturbances with much gas formation.
7. Damage to supportive ligaments, muscles, or fascia, from childbirth.

The degree of prolapse depends upon one or more of the above named factors, the time element, and the amount of damage to the supports. In the first and second stage of prolapse, the uterus becomes retrodisplaced and the intra-abdominal pressure is then exerted upon the anterior surface of the uterus, stretching the uterosacral and round ligaments and forcing the uterus to a lower degree.[2]

The primary stages of prolapse may be present before the menopause, but after the menopause, the uterus becomes atrophied and is more easily forced downward.

Symptoms

In the early stages of prolapse, the symptoms are usually mild, and may not be recognized. By examining the patient in a standing position, a beginning prolapse may be detected more easily. Later on, the symptoms are those of pressure, fullness, and some disturbances of the bladder or bowel functions.

Read at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1948.

In the third degree prolapse, the uterus can be forced outside the vaginal canal by straining, or it may protrude between the patient's thighs when in an erect position. The bladder is dragged down with the uterus and vagina forming a cystocele or a pocket back and below the pubis, causing retention of urine, frequency, and often incontinence.[5]

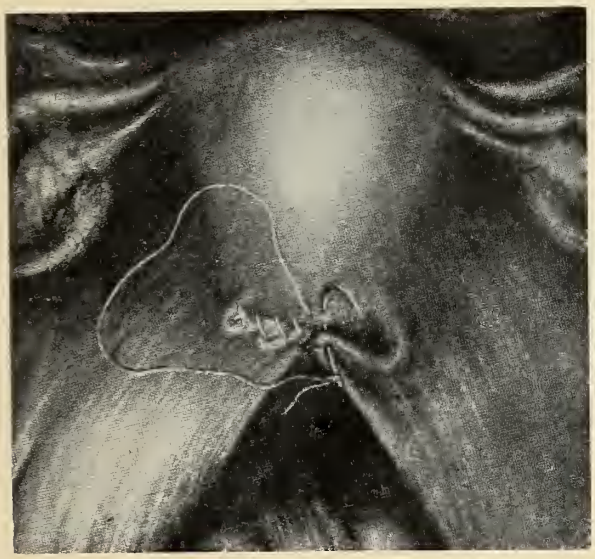

Fig. 1. Shortening the uterosacral ligaments in certain types of displacement.

Treatment

Treatment should be preventive, general and systemic, or operative. It would seem advisable that every woman of marriageable age should have a thorough pelvic examination in order to determine if there are any pelvic or abdominal factors that might lead to future prolapse of the uterus, so that preventive measures may be taken to obviate that possibility. These measures may include a change of occupation, diet, exercise, physiotherapy treatments, or possibly an operation.

An occupation that requires the woman to be on her feet much of the time or in a cramped or stooped position may favor the production of a procidentia.

The uterosacral and the round ligaments are important structures in maintaining the uterus in the normal antiflexed position, but if these structures are stretched or inadequate in their support, the uterus begins to assume an upright or retroflexed position. The intra-abdominal pressure then becomes a menace and an additional force, crowding the uterus downward. Therefore, it is necessary that an early operation be performed to shorten the uterosacral and round ligaments[1] (Figs. 1 and 2).

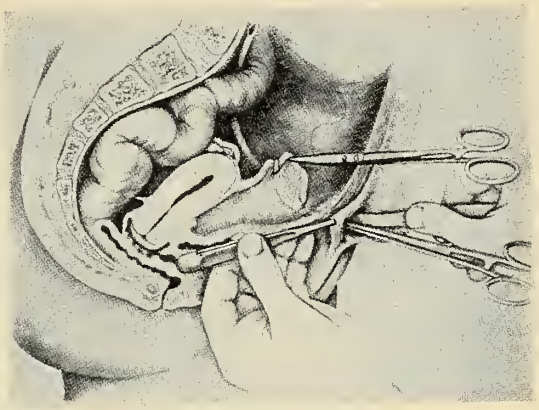

Fig. 2. Author's method of shortening the round ligaments for retro-displacement and moderate prolapse.

It is obvious that women who have borne children should be examined occasionally to note any tendency toward a prolapse. All lacerations should be repaired. I am convinced that there would be few cases of prolapse that would reach the third stage if all the safeguards heretofore mentioned were instituted. Nevertheless, we do see, and will continue to see, women in whom the third stage has been reached. It is in these women that we see the greatest distress, and the greater number of failures from operations. The problem then is: what are the remedies?

Usually these women have either reached the menopause or are not likely to have more children. Some operation that promises the best results without interfering with the function of any of the tissues or organs of the pelvis is desirable.

McKelvey[3] has suggested irradiation in certain cases. The sclerosing effect on the vaginal and other tissues of the female pelvis of married women would be an obvious objection and inadvisable.

The Baldy-Webster operation does not elevate the bladder sufficiently. The Gilliam operation is not applicable in these severe cases of prolapse of the uterus for the same reasons. The Watkins interposition operation is useful in some cases, but the uterus only acts as a plug to prevent the dropping of the bladder and does not act as an auxiliary support for the vagina. Patients still complain of a heaviness and fullness in the pelvis. After the menopause, the uterus is so atro-

phied that the results are poor, as the intra-abdominal pressure may force the small uterus with the bladder downward. Furthermore, in case malignancy should later occur, the removal of the uterus would be difficult and hazardous and less successful.

In a vaginal or abdominal pan-hysterectomy it is difficult to bring enough supportive structure together in a manner to adequately support a prolapsing bladder. Much scar tissue may develop that will stretch subsequently. About 30 per cent of patients so treated have trouble thereafter.

I have endeavored to develop an operation which augments all the natural supports of the uterus, and which seems to give more positive results than any other operation which has been used up to this time.

The operation is applicable to the following type of cases:

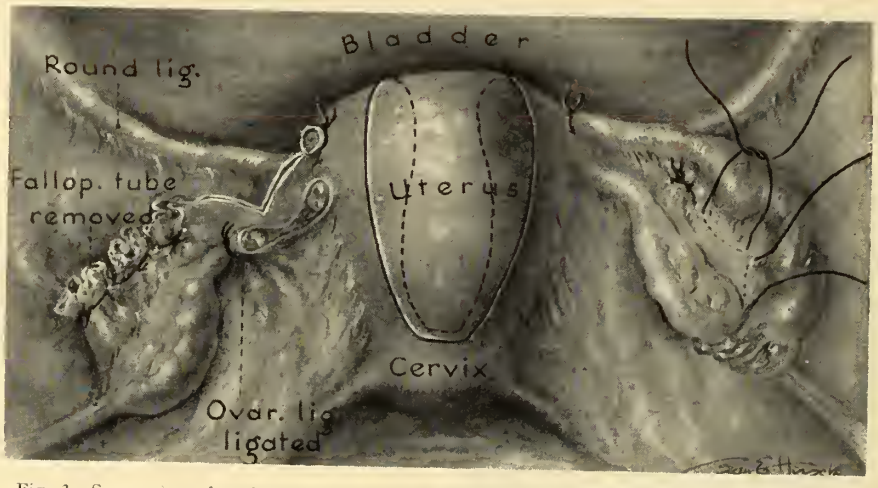

Fig. 3. Suspension of prolapsed uterus. Preparation of lateral uterine flaps. Semi-schematic.

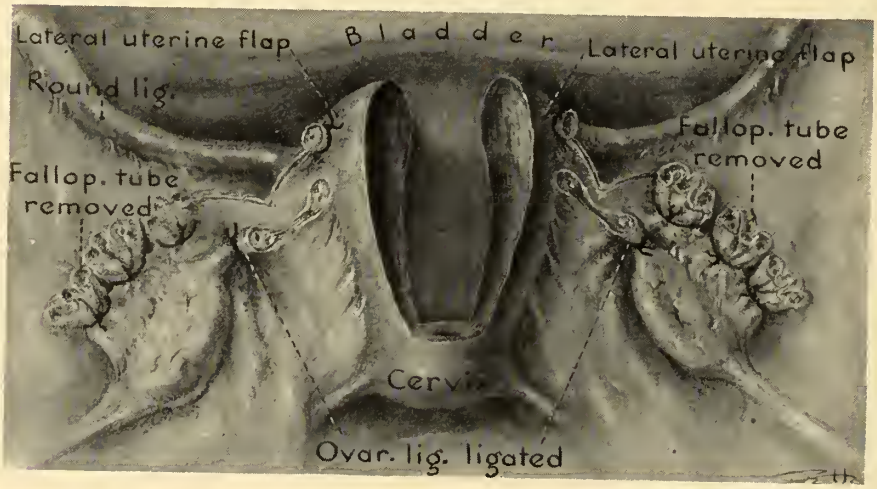

Fig. 4. Suspension of prolapsed uterus. Lateral uterine flaps after removal of body of uterus. Semi-schematic.

1. In cases of sterility.
2. In cases where no more children should be borne.
3. In nonmalignant cases.
4. In uterine prolapse with fibroids.
5. In women past the climacteric.

Operative Procedure

This operation first takes into consideration the repair of all the damage resulting from childbirth and the consideration of any intra-abdominal force that is instrumental in bringing about a prociden-

tia. It may be necessary to repair a perineum, amputate a cervix, cone out the mucous membrane of the cervical canal, and repair the anterior and posterior vaginal walls.

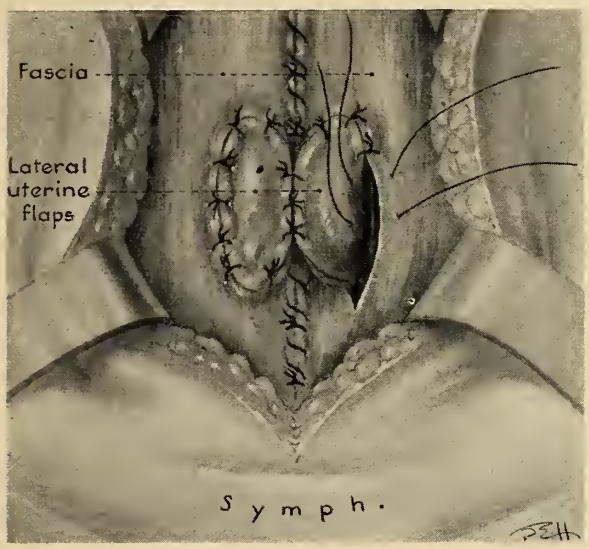

Fig. 5. Suspension of prolapsed uterus. Lateral uterine flaps anchored to external fascia.

A pelvic laparotomy is then performed to correct any abnormality within the pelvis. The tubes are removed and the ovaries separated from the uterus but not removed unless diseased. The midportion of the fundus of the uterus is excised, leaving the lateral portions (Figs. 3, 4, 5, and 6).

The mucous membrane of the canal is either coned out or cauterized. The lateral flaps of the uterus, together with the round ligaments, are then pulled through a slit in the lower abdominal muscles and fascia on each side above the pubis and 1.25 inches from the midline incision. These flaps are anchored at their exit through the fascia. The remaining portion of the cervix is then stitched to the perintoneum in the lower angle of the wound.

The abdominal incision is closed in the usual manner except for the skin. The lateral flaps coming through the fascia are folded over the fascia to the midline with the raw surfaces resting on the fascia and are there anchored. The skin is then closed over the flaps. This gives a firm positive additional support for the uterus and vagina, and elevates the bladder. There is no scar tissue to stretch, and the desired relief is obtained.

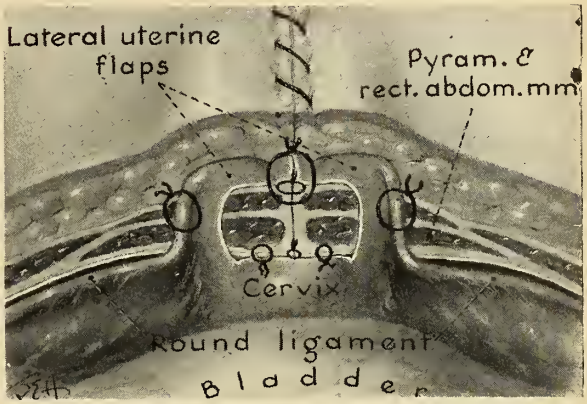

Fig. 6. Suspension of prolapsed uterus. Schematic cross-section of completed operation.

Conclusions

1. The laity, as well as the profession, has not always been satisfied with the treatment of uterine procidentia.
2. Too little attention has been given to the initial stages of uterine prolapse.
3. If the early symptoms were recognized and proper remedies applied, many subsequent cases of procidentia could be prevented.
4. In certain cases it is necessary to supply additional support to the restored normal ones.
5. In such cases the author has been satisfied with the operation which he has herein described.
6. This operation conserves all the necessary normal tissue and supports, and preserves the function of the vagina.
7. It permanently supports the uterus and bladder and gives satisfactory results.

PHEOCHROMOCYTOMA OF THE ADRENAL WITH SUCCESSFUL REMOVAL

Report of a Case

A. L. FORSGREN, M.D., W. D. NESSET, M.D., and D. M. ANDERSON, M.D.
Minneapolis, Minnesota

THE DIAGNOSIS of pheochromocytoma of the adrenal gland with subsequent operative removal has been reported with increasing frequency in recent literature. To date there have been approximately 70 such cases reported. Many excellent reviews of the subject have appeared, the most recent by Burrage and Halstad,[8] and Ganem and Cahill.[14]

The following case is presented as a typical example of the syndrome of paroxysmal hypertension associated with an adrenal tumor, and demonstrates the accuracy of certain diagnostic procedures.

Case Report

J. A., a man, aged twenty-seven, was admitted to the Minneapolis Veterans Hospital on April 1, 1948, complaining of weakness, flushed sensation, palpitation, headache, and nervousness occurring in sudden attacks since 1943.

In June 1943, while overseas in the South Pacific, he began to complain of these episodes. When seen by medical officers, the only positive physical finding was mild elevation of the blood pressure. On one occasion in January 1944, however, his blood pressure was found to be 225 mm. of mercury systolic and 140 mm. diastolic during an attack. He was hospitalized at this time, but returned to duty after 2 weeks when no further attacks occurred. Digitalis was given for 8 days following one episode without appreciable effect. At another time he was given iodine and phenobarbital for one week when his basal metabolic rate was found to be plus 35. After one week of treatment, the basal metabolic rate was reported to be normal.

After discharge from service he continued to have mild attacks almost every day. The attacks were gradually becoming more severe. He was employed as a surveyor and draftsman, but missed work frequently because of his complaints. In his own words he described the attacks as follows: "A typical attack begins with weakness in the knees and continues with a flushed sensation in the head and chest. The attacks are always accompanied by extreme nervousness. At all times any exertion during a mild attack brings on more severe symptoms. Occasionally the attacks are severe without exertion. At times the flushed sensation becomes painful. I developed pain in the solar plexus, base of the skull, and left eye. When attacks become severe, I usually vomit. An attack always leaves me fatigued, and unless I rest afterwards another episode follows. Individual attacks last from thirty seconds to ten minutes." Change of position had not been noted to produce attacks, but he had noted a pounding sensation in his chest each morning immediately after arising.

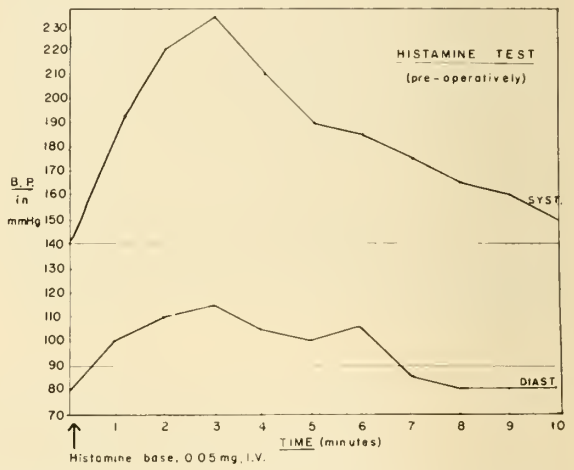

Fig. 1. Preoperative histamine test showing blood pressure response.

At the time of admission to the Veterans Hospital he was receiving compensation for "anxiety state." Several physicians who had seen him prior to admission made a diagnosis of hyperthyroidism. The basal metabolic rate was reported by one physician to be plus 85. He gave a history of jaundice while in service. There had been no recurrence.

Physical examination revealed a well developed and nourished male who did not appear acutely ill. He appeared extremely concerned about his condition. The patient wondered if his complaints were associated with a mental condition, but did not believe they were. The blood pressure ranged between 120 and 150 mm. of mercury systolic and 75 to 100 mm. diastolic. With change in position marked change of force and rate of heart beat was noted. Massage of the renal areas did not produce an attack. A fine tremor of the hands was noted, but no abnormal perspiration was seen. A small amount of mucopurulent white discharge was expressed from the urethral orifice. No other abnormalities were noted.

A complete blood count, sedimentation rate, and urinalysis on admission were normal. The blood Kahn test was negative. Blood cholesterol was 208 mg. per cent. A six-hour glucose tolerance test showed a normal curve. The basal metabolic rate on three successive days

was minus 2 per cent, plus 1 per cent, and minus 2 per cent. Bromsulfalein retention was 5 per cent in forty-five minutes. Serum proteins were normal. Cephalin cholesterol flocculation test showed 1 plus in twenty-four hours and 3 plus in forty-eight hours. A urethral smear revealed Gram negative and positive cocci, but no N. gonorrhea. A routine electrocardiogram revealed right axis deviation. No other abnormalities were noted.

During the first week of hospitalization the patient remained a diagnostic problem. It was thought that hyperthyroidism had been ruled out. Paroxysmal hypertension due to an adrenal tumor was suggested as a possible diagnosis. The patient had experienced no attacks up to this time while in the hospital. A histamine tolerance test was then done according to the method of Kvale and Roth. Histamine base, 0.05 mg. in 0.5 c.c. normal saline, was injected intravenously, and blood pressure readings were taken at one-half and one minute intervals until the preinjection blood pressure was reached. The result of this test is shown in Figure 1. The result was thought to strongly suggest an adrenal tumor. When this test was repeated, the blood pressure rise was almost exactly the same. The blood sugar, fifteen minutes after injection of histamine, showed a rise of 24 mg. per cent above the preinjection level. A cold pressor test showed a 30 mm. rise in the systolic pressure and a 20 mm. rise in the diastolic pressure one minute after his hand was placed in ice water. Three minutes later the blood pressure had reached its basal level. Tetra-ethyl-ammonium chloride in a dose of 100 mg. was injected intravenously. Blood pressure readings at minute intervals after injection showed only a 10 mm. rise in systolic and diastolic pressures two minutes after injection. The blood pressure gradually fell to 10 mm. below the basal pressure in fifteen minutes. Twenty-five days after admission the patient was seen during an attack. He complained of a burning sensation in his upper chest, palpitation, weakness, and a flushed sensation. The blood pressure was 220 mm. of mercury systolic and 110 mm. diastolic when first seen. In the next ten minutes the blood pressure dropped to 126 mm. of mercury systolic and 68 mm. diastolic. An intravenous pyelogram done a few days later was reported to be normal (Fig. 2). Perirenal air insufflation was then done. Six hundred c.c. of air were injected into each perirenal space. X-rays showed a globular mass overlying the upper pole of the left kidney (Fig. 3). On the basis of these findings he was sent to surgery with a diagnosis of pheochromocytoma of the left adrenal gland.

Preoperatively the patient was given nembutal, grains 1½ orally, and morphine sulfate, grains ¼, and scopolamine, grains .01, hypodermically. In addition he received adrenal cortical extract (Eschatin) 10 c.c. intramuscularly and 1000 c.c. of normal saline intravenously on the morning of operation.

Operation was performed on May 5, 1948. Anesthesia was induced with pentothal sodium and maintained with nitrous oxide and ether. Induction was accompanied by three episodes of laryngospasm. The blood pressure on one occasion became elevated to 200 mm. of mercury systolic and 100 mm. diastolic, and at another time to 240 mm. systolic and 130 mm. diastolic. These hypertensive episodes were controlled by injecting pentothal intravenously. Through a left lumbar incision a vascular tumor measuring 5 cm. in diameter was found lying inferior and anterior to the left adrenal gland. It was

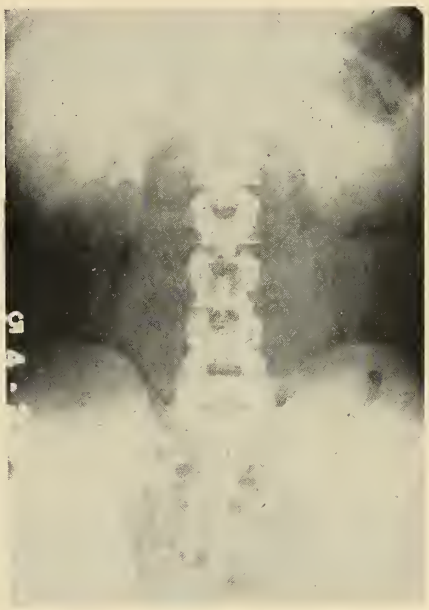

Fig. 2. Normal appearing intravenous pyelogram failing to show tumor.

attached to the adrenal gland at only one point, but was free from the left kidney. Necessary manipulation about the tumor provoked a third paroxysm of hypertension, and the tumor was subsequently removed. No other tumor tissue was found. Immediately after removal of the tumor the blood pressure dropped to 90 mm. of mercury systolic and 50 mm. diastolic. Before leaving the operating room he was given 1 c.c. epinephrine in oil 1:500, intramuscularly, ephedrine sulfate 25 mg. intramuscularly, and ephedrine sulfate 25 mg. intravenously. During the operative procedure 1500 c.c. of whole blood were given intravenously. Immediately following operation he again received adrenal cortical extract 10 c.c. intramuscularly. During the first twenty-four hours postoperatively 3,000 c.c. of solution containing 5 c.c. of 1:1000 epinephrine in 1000 c.c. of normal saline was given in a constant drip intravenously. The rate of flow was regulated according to the blood pressure readings. Readings were taken every 5 minutes during this time. During the first 24 hours postoperatively the blood pressure was maintained between 90 and 120 mm. of mercury systolic and 50 and 75 mm. diastolic. At no time did the systolic blood pressure drop below 90 mm. of mercury. He became ambulatory on the 2nd postoperative day. On the 3rd postoperative day he developed a thrombophlebitis of the veins in the right cubital fossa. Dicumarol therapy was begun at once. On the 7th postoperative day he developed a thrombophlebitis of his left lesser saphenous vein. Aside from this there were no complications.

Thirteen days postoperatively the histamine and cold

pressor tests were repeated. The histamine test, as shown in Figure 4, in contrast to the preoperative test, showed an initial drop in blood pressure followed by a slight rise. This was considered to be a normal histamine response. The cold pressor test showed no appreciable change from that done preoperatively. The basal metabolic rate after operation was plus 2 per cent. Cephalin cholesterol flocculation test revealed 1 plus in 24 hours and 2 plus in 48 hours. An electrocardiogram after operation showed no change from that taken preoperatively.

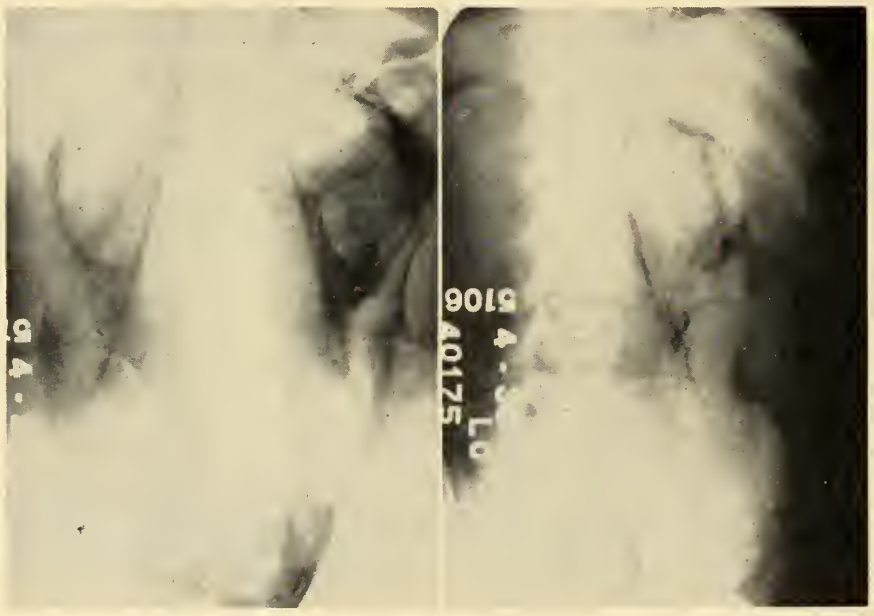

Fig. 3 *A.* Anterio-posterior roentgenogram following perirenal air insufflation showing tumor mass overlying upper pole of left kidney. *B.* Left oblique view.

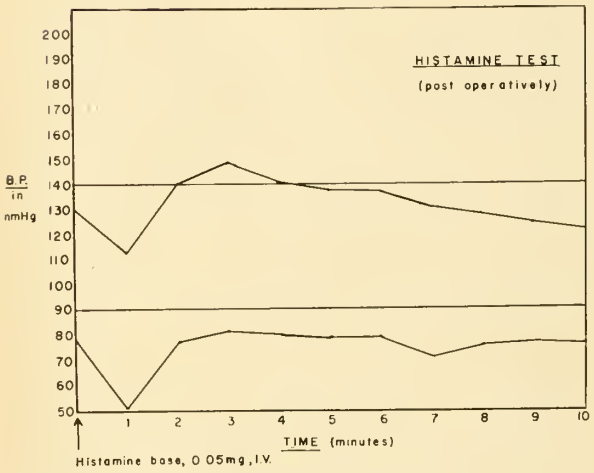

Fig. 4. Postoperative histamine test showing blood pressure response.

The tumor, as reported by the Pathological Department, consisted of a spherical mass 5 cm. in diameter (Fig. 5). The total weight was 66 gms. It appeared slightly globular and well encapsulated in its entirety. On cut section the tumor mass presented a pale grayish moist appearance with purple mottled areas which were softer in consistency, and one cystic area 1 cm. in diameter containing bright red fluid. The tumor as a whole had a rubbery consistency. Microscopically (Fig. 6), sheets of large polygonal cells with relatively large hyperchromic, vesicular nuclei were seen. The cell membrane was distinct. The cytoplasm was abundant and acidophilic. Other cells had a bizarre appearance. They were large and spindle shaped. The nuclei were larger and more hyperchromic. These cells were separated by what appeared to be empty spaces. The pathological diagnosis was pheochromocytoma of the adrenal gland.

The patient was discharged from the hospital on June 2, 1948, without medication. Symptoms and signs of thrombophlebitis involving the veins of the right arm and left leg had subsided almost completely when discharged. The urethral discharge was thought to be due to a meatitis, non-venereal. The patient stated that he had no symptoms suggesting even a mild attack, such as experienced in the five years preoperatively. The pounding sensation in his chest noted upon arising in the morning, experienced before operation, was no longer present. His blood pressure during the last week of hospitalization averaged 120 mm. of mercury systolic and 75 mm. diastolic.

Discussion

This patient resembled numerous others in the literature in that, during the illness, diagnoses of anxiety state, hyperthyroidism, and essential

hypertension were made. Hypermetabolism, abnormal glucose tolerance curve, and glucosuria[16] are reported in a number of cases, but these abnormalities were not demonstrated in our patient during our observation of him. The BMR of plus 85 reported a few months prior to hospitalization is difficult to interpret in view of 3 normal BMR's during the patient's hospital stay. The increase of 24 mgs. per cent in the blood glucose level during a histamine-induced attack may have been significant, but does not approach the hyperglycemia which has been reported.[3,18]

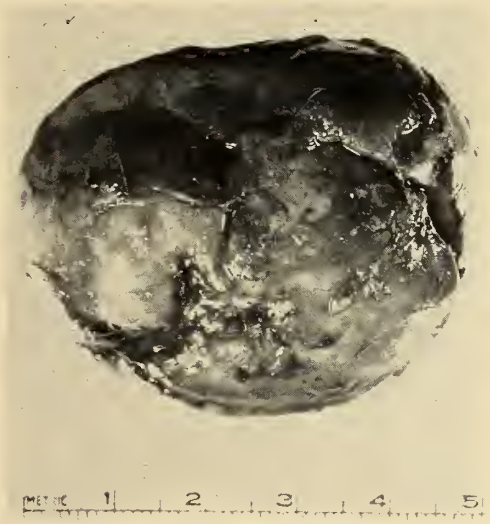

Fig. 5. Tumor removed at operation.

Our results during the histamine test were in accord with those of Roth and Kvale.[25] Although the patient's symptoms during the test were not identical with those during a spontaneous attack, they were similar. The blood pressure response was striking, and provided a distinct contrast to that following the cold pressor test. Roth and Kvale have emphasized the importance of contrasting the histamine test with the cold pressor test, since patients with essential hypertension may exhibit a pressor effect following histamine which is approximately similar quantitatively to their response to the cold pressor test. The postoperative histamine test in our patient was comparable to that of a normal person.

Our experience with the use of tetra-ethyl ammonium chloride in an attempt to precipitate paroxysm of hypertension did not concur with that of LaDue.[21] His patient responded to 100 mgs. of tetra-ethyl ammonium bromide intravenously in much the same way as he did to histamine. Our failure to precipitate an attack suggests that histamine remains as the most reliable means of precipitating attacks of paroxysmal hypertension.

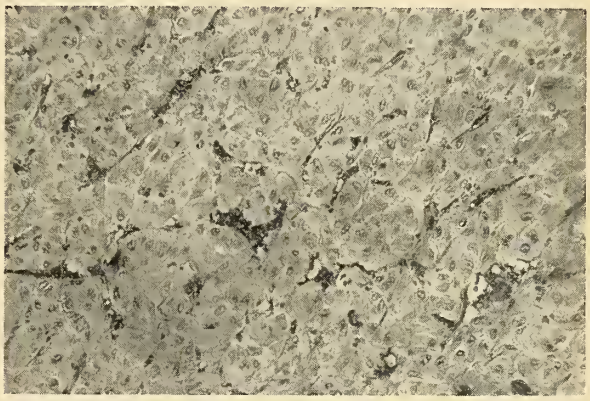

Fig. 6. Section of tumor.

The value of perirenal air insufflation was again demonstrated. With this technique the tumor was well visualized while intravenous pyelography failed to suggest the presence of an adrenal tumor in spite of excellent visualization of the renal shadows. The air insufflation was well tolerated and although subcutaneous emphysema was demonstrable following the procedure, the patient's symptoms were minimal.

The benzo-dioxane group of drugs was not used as a diagnostic test in this patient, primarily because he presented the picture of paroxysmal, rather than fixed, hypertension. Many authors, particularly Thorn and Hindle,[29] Green,[16] and Phillips[24] have demonstrated that fixed, chronic hypertension, not unlike essential hypertension, can dominate the clinical picture of a patient with pheochromocytoma. The observations of Goldenberg, et al,[6] are of great importance in this group of patients. They demonstrated a qualitative difference between the effect of benzo-dioxane on epinephrine-induced hypertension, as due to a pheochromocytoma and essential or renal hypertension, the drug producing a fall in blood pressure in the former and either no effect or a pressor effect in the latter. Ganem and Cahill[14] confirmed these observations and reported a case where the use of benzodioxane was instrumental in the demonstration of residual tumor tissue in a 12-year-old child who had had a pheochromocytoma removed. Fixed hypertension had persisted after the first operation. The benzodi-

oxane test might well be considered in the study of patients with essential hypertension, and should certainly be used when any factors in the patient's history or findings suggest the possibility of pheochromocytoma.

Surgical removal of pheochromocytoma is characterized by two types of vascular response. During the early stages of operation and particularly in the course of manipulation of the tumor, severe paroxysms of hypertension may ensue. The question might be raised whether benzodioxane with its adrenolytic action, of brief duration, might be used to counteract these paroxysms of hypertension during operation. Following removal of the tumor, a shock-like state with marked hypotension is common, generally thought to be due to epinephrine lack. However, decreased blood volume related to prolonged severe vasoconstriction,[8,13] as well as heart failure secondary to extreme hypertension[2] have been postulated as the mechanism producing the shock. Surgical fatalities have resulted from both severe hypertension and postoperative shock. Epinephrine as a supportive measure during this stage of hypotension has been almost universally used. In addition Thorn and Hindle,[29] Biskind, et al,[5] and others have recommended the use of adrenal cortical extract preoperatively and postoperatively. Our patient received adrenal cortical extract in this manner. Following removal of the tumor hypotension developed and he received large amounts of epinephrine and ephedrine. Constant intravenous infusion of a dilute solution of epinephrine in saline with appropriate variations in rate appeared to be a satisfactory means of controlling the unstable postoperative blood pressure in our case.

Both transperitoneal and lumbar retroperitoneal approaches to the adrenal area have been used. When the tumor has been well localized, as was in the case of our patient, adequate exposure is obtained by the usual kidney incision. When exploration of both adrenal areas is desired, the transperitoneal approach may be indicated. The operative mortality has progressively decreased. Up until 1936 there was a 37 per cent mortality rate among nineteen patients. Of approximately twenty patients subjected to operation and reported during the past two years, only one operative death has occurred.

Successful removal of a pheochromocytoma promises a cure in all but a very few cases. Calkins and Howard[10] reported a remarkable instance where a woman and her niece both had pheochromocytomas removed and both had recurrent symptoms requiring reoperation. Additional chromaffin tumor tissue was found in both patients. Ganem and Cahill's case also required a second operation for an extra-adrenal chromaffin cell tumor. The great majority of pheochromocytomas are benign but malignant changes do occur. Malignancy is almost always associated with bilateral tumors.[27]

The increasing number of cases reported suggests that these tumors are more common than was believed a decade ago. This together with the decreasing operative mortality emphasizes the importance of considering the diagnosis and of making use of the available diagnostic procedures when indicated.

Summary

The case is presented of a twenty-seven-year-old male with a four-year history of paroxysmal hypertension. The preoperative diagnosis of pheochromocytoma was made with the aid of the histamine test and x-ray visualization of the tumor by perirenal air insufflation. Successful operative removal has apparently resulted in a complete cure. Certain aspects of diagnosis and treatment are discussed.

Case Report

CASE RECORD OF ST. MARY'S HOSPITAL, DULUTH

Clinico-Roentgen Pathological Presentation

Edward L. Tuohy, M.D., *Co-ordinator*
Wm. V. Knoll, M.D., *Pathologist*

Moses Barron, M.D., University of Minnesota, Minneapolis
Outlining Problems and Differential Diagnosis

Case Presentation

The case is that of a man, aged forty-three, with a decisive critical epigastric pain (for details *vide infra*). The dates, April 22, 1948, to May 8, 1948, cover the period of his acute illness up to his death.

The previous health and history contributed nothing determinative, except an indefinite reference to spells of "heart burn," helped by food and soda.

After eight days of acute illness, signs of gastrointestinal hemorrhage supervened.

For the next few days the illness took on serious implications: shock, tachycardia, hiccoughs, spread of pain over the abdomen, a failure to respond to blood and other transfusions.

In an attempt to find the source of hemorrhage an unsuccessful upper abdominal exploration was done.

There was no opportunity for gastrointestinal barium roentgen studies. The laboratory profiles appear in the discussion.

Dr. Moses Barron: I have been given this detailed case history for differential diagnosis, and from it I shall quote and comment. "A forty-three-year-old Great Lakes seaman on April 22, 1948, developed a sudden, sharp, epigastric pain, localized beneath the tip of the sternum. It did not radiate. This was associated with emesis immediately after every attempt to eat. On resting the pain would diminish, finally disappearing, only to recur when he ate."

The history so far tells of a sudden epigastric pain in the lower sternal region which recurred apparently with the swallowing of food. There are a number of things which have to be taken into consideration: carcinoma of the esophagus or carcinoma at the cardiac end of the stomach; carcinoma of the body of the stomach or peptic ulcer of the gastric or duodenal type; one also has to consider a dissecting aneurysm of the arch or thoracic aorta, a low esophageal diverticulum or hiatus hernia.

For carcinoma of the esophagus the onset was too sudden. There was no history of difficulty in swallowing solids as compared with liquids. The story thus far is against carcinoma of the esophagus.

I read further from the history: "The pain did not come on with effort." This statement is made to help rule out coronary sclerosis with either anginal attacks or coronary thrombosis as a possible explanation. And further: "These pains became so severe that he was hospitalized in another city. Two days before admission to St. Mary's on April 30, 1948, and eight days after the onset of his present illness, he had several tarry stools, and the day preceding admission to St. Mary's he developed hematemesis and that led to his reference here." This additional history rules out the possibility of either coronary disease or a dissecting aneurysm. There would not be hematemesis or tarry stools. An aortic aneurysm which may gradually penetrate into the stomach might have to be considered *but this is very unlikely*. The hematemesis would have appeared at once and not a week later, and there would have been a history of distress, characteristic of aneurysm, which was not present. I now look at the meager past history and it adds little: "The patient had had 'heartburn' for many years. He could relieve it with soda between meals, or by eating. This had not inconvenienced him greatly and he had never sought medical advice regarding it. There was no history of previous surgery, serious illness or accident. The systemic review otherwise was entirely negative."

I now come to the physical examination from which we expect so much in these days of exalted laboratory and roentgenological techniques: "The patient was a well-developed, well-nourished white male who complained of sharp epigastric pain and who had evidence of hematemesis, some pallor—pulse regular but a little fast—some blood emerging from the corner of the mouth on one side. Blood pressure was 140/76; pulse 136; temperature 102, respirations 28. Neck was negative, chest showed equal bilateral expansion and the lungs were normal to percussion and auscultation. The heart showed no enlargement to percussion. There were no thrills, murmurs, or arrhythmias. No masses were palpable in the abdomen. The kidneys, liver, and spleen were not palpated. The patient showed moderate epigastric tenderness and the abdomen was tense but not rigid.

"Laboratory data: red blood cells, 1,840,000; hemoglobin, 4.9 grams; white cells, 16,100; polymorphonuclear cells, 92; 6 lymphocytes and 1 monocyte. Urine: specific gravity, 1.018; 5-6 white cells and 1-plus sugar, otherwise negative. Stool was 4-plus for occult blood."

The patient was not rallying; the clinical course continued stormy. "Shortly after admission the patient developed hiccoughs. He continued to vomit blood the

Presented at the annual meeting of the Northern Minnesota Medical Society, Duluth, Minnesota, August 20-21, 1948.
The case presentation has been epitomized and abridged for publication to enable Dr. Barron to read into his discussion the essential clinical data, and thus avoid duplication.

first night of hospitalization and also had four bowel movements, all of which contained large amounts of dark red blood. The next morning (May 1, 1948) the blood pressure was 90/40 and the pulse was 128. Two blood transfusions were given that morning, and an operation was performed at noon. The patient survived a week after his operation. The operative details are not given; but I am assured that *death was NOT due to "an operative misadventure."*

The additional history helps to rule out some of the other conditions mentioned above. Carcinoma of the cardiac end of the stomach would give a slowly progressive development of dysphagia. The dysphagia would not be as intense. A characteristic feature of the distress here is the pain during the act of swallowing which ends abruptly soon thereafter. The massive hemorrhage also makes carcinoma less likely. In carcinoma of other parts of the stomach the distress starts sometime after the ingestion of food and continues for a considerable period after. Peptic ulcers of the stomach or duodenum frequently cause distress that is related to meals, but it usually starts from fifteen minutes to three hours after taking the food. A para-esophageal diverticulum, especially one low down, has to be considered. This generally has a longer history, and the course is much less intense than in this case. The possibility of ulceration of the diverticulum resulting in hemorrhage must be kept in mind. But here again the dysphagia from the act of swallowing is not so abrupt in onset and in termination.

Conclusions and Summary

There is one condition which has thus far not been mentioned but which fits in almost perfectly with the character of the distress, the history of the onset and the absence of physical findings. That condition is a *peptic ulcer of the lower end of the esophagus.* There are very few if any conditions which result in this peculiar symptom of a severe dysphagia during swallowing with a very abrupt onset and termination, and almost complete relief between periods of deglutition. The finding of a definite leukocytosis has been brought up, and this can be explained by a perforation of the ulcer with the infection spreading into the surrounding tissues of the mediastinum.

Therefore in making a differential diagnosis in this case I would place first and foremost a *perforating ulcer of the lower end of the esophagus,* and the other conditions in order of their importance would be ulcer in the cardiac end of the stomach, ulcer of a para-esophageal hernia, carcinoma of the cardiac end of the stomach, peptic ulcers with perhaps perforations of the stomach or duodenum, carcinoma of the fundus or pyloric part of the stomach.

The Anatomical Diagnoses

1. Peptic ulcer of lower end of esophagus.
2. Perforation of ulcer via the esophageal hiatus.
3. Fatty necrosis from pancreatic invasion.
4. Mediastinitis and pleuritis with pneumonitis from regurgitation of pancreatic fluid into the chest via the route of perforation and extension.

Pathological Discussion

Dr. Wm. V. Knoll: Dr. Barron in his excellent analysis of this case has already pointed out or suggested the pathological picture found at necropsy. The ulcer of the esophagus, 1 by 2 cm. in size and located 1 cm. above the cardia, had perforated and permitted the escape of the content of its lumen into the mediastinal tissues. Apparently fluid from the stomach and duodenum with its pancreatic ferment had regurgitated into the mediastinal tissues via this perforation resulting in a manifestation of fat necrosis involving the lower two-thirds of the left pleural cavity. Dark brown fluid to the extent of 800 c.c. filled the left pleural space and 500 c.c. of similar fluid within the right pleural space. The right side however, showed no fat necrosis, but a hazy parietal pleura. Both lungs present dull, hazy pleural coverings, having been changed by the digestive fluids. The right lung weighed 800 gm. and the left 650 gm. Both lungs disclosed marked consolidation, and partial collapse was noted in the left side. Granular patches of pneumonitis were present.

The pericardial sac was slightly adherent to the 400 gm. heart by fibrinous adhesions.

The inflammatory process had made its way through the esophageal hiatus into the abdomen. There was no hiatus hernia. Along the lesser curvature of the stomach there was a mass of adhesions involving a portion of the greater omentum which connected the mass with the head of the mesenteric tissue at the ligament of Treitz. This mass was associated with foci of fat necrosis. The peripancreatic and periduodenal fatty tissue presented similar foci of fat necrosis, and the mesentery and mesocolon participated in the process but to a lesser extent. The head of the pancreas was in part involved in beginning necrosis along its periphery. The liver, enlarged to 1800 gm., was average in appearance, as was the gall bladder, which contained three calculi varying from 1 to 2 cm. in diameter.

Histological studies of the various tissues supported the listed findings but added no further information.

Chronic ulcer of the esophagus is not a common finding in necropsy studies. In a study of case reports and summaries there is general agreement that such an ulcer may follow abnormal entrance of hydrochloric acid into the distal end of the esophagus. This regurgitation of hydrochloric acid is most commonly associated with a congenitally short esophagus or a diaphragmatic hernia or both. The presence of aberrant gastric mucosa in the lower one-third is another etiological factor. In Chamberlin's report on seven cases, found over a period of ten years at the Lahey Clinic, six were associated with short esophagus or diaphragmatic hernia or both and one only was associated with aberrant gastric mucosa. Other possible factors have been listed such as chronic recurrent vomiting, pyloric stenosis, or an abnormally patulous cardia. Some case reports call attention to the co-existence of a chronic gastric or duodenal ulcer.

Since 1939 the diagnosis of esophageal peptic ulcers has been greatly influenced by the following five criteria presented by Chamberlin of Boston: (1) the ulcer must

History of Medicine In Minnesota

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

(Continued from January issue.)

Dr. Howard Bell.—Nora Guthrey, in her *Notes, Fillmore County,* has given all known data concerning Dr. Bell, who evidently left Albert Lea in a very short time, for the only record of his activities in Freeborn County is contained in the following newspaper item of 1885, "An accomplished physician, Dr. Howard Bell located at Albert Lea and is being introduced into practice by Dr. F. A. Blackmer."—*Standard,* July, 1885.

Dr. John P. von Berg was born at Hazel Green, Wisconsin, July 15, 1858. He died at Albert Lea of carcinoma of the stomach and liver, December 4, 1929. His father, George Leonard von Berg, was born in Hatershofen, Wurtemburg, Germany, and migrated to America and married Elizabeth Nicolas, at Hazel Green, Wis. They had four children: Dr. John P.; George, D.D.S., Charles City, Iowa, died 1940; Lydia B. (Werk), Charles City, died 1893; and Leonard, also of Charles City, died 1889. Dr. John P. von Berg married Dorthea Dittmer of Guttenberg, Iowa, June 5, 18—. To them five children were born: Leonard E., D.D.S., Charles City; John Phillip, D.D.S., Albert Lea; Nora B. (Hickman), wife of a minister in Saint Paul; Eva Lee (died 1938), who was head of the department of the High School of Commerce, Portland, Oregon; and Dorthea E., Dean of Girls, Vancouver, Washington, High Schools and Secretary of the Western Division of the Deans' Association.

Dr. von Berg received his early education in the public school at Charles City, Iowa. Then he attended the normal school and the General English College, of Galena, Illinois. Finally he entered Morningside College at Sioux City, Iowa, where he was an honor student. He attended Hahnemann and Rush Medical Colleges in Chicago and graduated in 1884. He also made use of his normal school training and spent some time teaching in the public schools of Clinton County, Iowa. He attended postgraduate schools in Chicago in 1890, in New York in 1895, and in San Francisco and Philadelphia in 1899. He received license to practice in Iowa in 1884 and in Minnesota in 1885. He held memberships in local and state medical societies and in the American Medical Association. He was a charter member of Freeborn County Medical Society and served as its first treasurer. He held the office of president from 1909 to 1922. He was a member of Naeve Hospital staff. He served as county coroner, was a member of the board of education and a director of the Citizens' National Bank of Albert Lea. He also served on the pension board of the Spanish American War, from 1900 to 1906.

He was an inveterate reader in medicine and possessed one of the finest of private medical libraries, including books and periodicals from leading German universities. He had the first x-ray apparatus and established the first x-ray laboratory in Albert Lea. He was a solid general practitioner throughout horse-and-buggy days and gave special attention to obstetrics. He loved fine horses and

always drove spirited spans in caring for his large practice. Fees were small during the greater part of his allotted work days, but he attended diligently and faithfully all who called him, whether with or without prospect of remuneration.

He was a tall stately gentleman, always neatly dressed, and wore a well-groomed full beard. He was slow and careful of speech, but possessed a brand of dry wit and humor that intrigued his friends, who often hailed him in passing in the hope of hearing a funny story or experience. He said to one of his good friends one day in discussing a fellow townsman, "That man talks too much." The friend answered, "Well, Dr. von Berg, you will never be hanged for what you do not tell." The doctor replied, "But I would rather be hanged for that than be accused of overstatement." An anxious mother asked him eagerly concerning the medication for her child, "Doctor, what is this medicine for?" "That is for scarlet fever," he replied. "And what is this other one for, please?" "That is for scarlet fever too," he replied.

But he was a kindly man and his heart was in his profession. He served in love of humanity, but with firm gentleness and gentle firmness. As long as he was able to practice, he continued his habit of standing by in the sick room when his patient was dying. Often sacrificing his own need of sleep and rest, he, by his presence, would add comfort and courage to that afflicted home, sitting quietly with his hand at the fleeting pulse. With his passing passed also the last in line of that nobility around here.

Dr. von Berg was a deeply religious man, a member of the Methodist Church and the Knights of Pythias. During the forty-four years of his practice, his name and character were without spot or blemish. Of him his daughter Eva Lea writes:

"Think of the wealth of good he has done, the fullness of the life he has lived, the thousands whose lives he has touched and blessed. How unstintingly he gave of his time and money to those in need. His integrity was without fear. What a heritage he has left us."

A very short time before he took to his last sickbed, the writer met him on the street. "What a strange coincidence," he said, pulling out his watch and looking in the distance. "The court house clock has stopped, my watch has stopped, my income has stopped, and very soon, now, I shall stop." Then he passed on with a smile.

"Dr. ——— Nichols, from Red Wood Falls, located at Hartland, comes well recommended, and already has a large practice. Will open a drug store."—*Standard*, June, 1888.

"Dr. Nichols skipped about 12 M. Quacks and humbugs in the medical line better steer clear of Hartland."—*Standard*, July 12, 1888.

"Dr. Hetlesaether, of Des Moines, Iowa, came to Alden in 1888, speaks Scandinavian and German."—*Enterprise*, February, 1888. Evidently Dr. Hetlesaether remained only a very short time as there is no record of a continued practice.

Dr. John Herman located at Albert Lea in the early part of November, 1883, but in the same month moved to Spink County, South Dakota.

Dr. O. H. Olson of Northwood, Iowa, located at Albert Lea in 1888. He was recommended as a finely educated and experienced physician. "At first his practice was successful, but it soon became known that he was an addict to

morphine and cocaine. About a year later his mind became affected and after a murderous attack on his wife, he was removed to an asylum in Ohio."—*Extracts,* Nora Guthrey. According to the medical directory, 1900, Dr. O. Hansteen Olson was located at Erskine, Polk County.

Dr. Charles Monroe Cannon, an accomplished physician, surgeon, and gentleman, located at Alden in 1887. He evidently returned to continue his medical studies at Bennett Medical College, Chicago, from which he graduated in 1888. He married Edith Morey, a member of an early pioneer family at Alden, bought the residence of Dr. G. A. Stevenson, and decided to locate and become a permanent citizen there. He commanded the respect of the people of the community, who considered themselves fortunate in securing such a capable and worthy citizen. In 1889 he received the appointment, under Congressman Dunnell, of physician in charge of the White Earth Indian Agency. In May, 1890, he re-located at Alden and continued to practice there until February, 1893, when he moved to Saint Paul, where he practiced until his death in 1923. He was a member of the State Board of Medical Examiners from 1902 to 1905.

"**Dr. Burt Robertson,** one time at Alden, died in Graceville, Minnesota, October 14, 1896, of paralysis. He was editor of a paper at that place and was also a noted orator in that section of the country."—*Enterprise,* October, 1896.

Dr. J. M. Todd.—The family "Todd" has a genealogy that dates back to Scotch ancestry prior to the fourteenth century. Some of the Todds migrated to England, and the earliest known English ancestor, John Todd, was High Sheriff of York, England, in 1390. Members of this Todd family came to America and settled in Massachusetts, Virginia, and Connecticut.

Christopher Todd, born at Pontefract, England, in 1617, was the first to come to America. He landed in Boston in 1637 and settled at New Haven, Connecticut, where he became a farmer, miller, and baker. The Connecticut Todds were progenitors of their namesakes in these sketches. Many of their line became prominent in the pulpit and in medicine. A number served with distinction during the Revolution. Rev. James Doeg Todd, father of the two doctors, James M. and William E., was born at Mina, Chautauqua County, New York, November 22, 1826. In 1843 the family moved to a farm at Mount Hope, near Apple River, Illinois. Rev. Todd studied theology with the first class enrolled at Beloit Seminary, Beloit, Wisconsin, and from 1859 served congregations in Wisconsin, Iowa, Minnesota, Kansas, and finally in Maryland up to the time of his death at Hagerstown in 1914. He had seven children, of whom Drs. J. M. and Wm. E. Todd were the oldest.

Dr. James Marcus Todd was born on the farm near Mount Hope, Illinois, October 12, 1858. He studied at Beloit College and from there went to Northwestern University, where he attended the medical school, from which he graduated in 1887. In the meantime he had read medicine with Dr. Wedge, and on his ascent as preceptor, went to Madison, Minnesota, where he practiced part time through 1886 and 1887. After graduation he returned to his practice at Madison until 1889, when he located at Albert Lea. Here he married Nora Abbot. They had one son, Russel Webster Todd, who was born in Madison, Minnesota, in January, 1888, and graduated from Princeton University in 1910 and from Columbia Law School in 1913.

Dr. James M. Todd was a man of unusual natural ability, was well grounded in the arts and sciences, and possessing, as he did, an appealing personality, soon

made his presence felt in the field of medicine and also in civic affairs. By his skill and devotion to the duties of his profession, he won the confidence of the public to an extent seldom realized, and early in his career drew commendations from every quarter. For several years he was president of the Board of Health of Albert Lea. He was urgent about quarantine and the care of infectious and contagious diseases and also about general sanitation relating to sewage disposal, dumping grounds, the regulation of meat markets, and the slaughtering of meat animals.

In 1894 he built and equipped a small hospital, called Albert Lea Hospital. He advertised this in the weekly papers by showing a photograph of his building, "a thoroughly equipped hospital with trained nurses, electric and medicated baths, and with every convenience for treating chronic and surgical diseases."

Attempts had been made, with Dr. Todd's unqualified support, to interest the public in buying and maintaining a public hospital for the benefit of all and open to all. Dr. Todd's little hospital received favorable consideration, but negotiations fell through, and the discouraged doctor sold his hospital in 1897 and went to New York City.

In New York City he joined his brother, David R. Todd, in forming the Center Realty Company, which built some of the city's outstanding apartment houses, apartment hotels, and office buildings, such as the Wentworth, York, Bismark, Severn, Van Dyke, and Equitable Trust Company. With the retirement of his brother in 1916, Dr. Todd formed a new partnership with Hugh S. Robertson, and three years later they joined the firm of Todd, Irons, and Robertson, headed by John R. Todd, another brother. This firm built the Central Building at 25 Broadway and reconstructed the Guarantee Trust Building. Next the firm became the Todd, Robertson, Todd Engineering Company in 1922, when Henry C. Irons left it. This firm concentrated in mid-town construction and built the Ritz Tower, the Postum Building, the Barclay Hotel, and the Graybar building.

In 1928 this firm, with the firm of Todd, Brown, Inc., of which Webster B. Todd, Dr. Todd's nephew, was a member, contracted for the reconstruction of Williamsburg, Virginia, where John D. Rockefeller, Jr., financed the rebuilding of the Colonial Community in its original architecture.

Until his retirement in 1937, Dr. Todd was particularly active in the mechanical and engineering development of Rockefeller Center, which Todd, Robertson, Todd, and Todd and Brown managed since construction began in 1931. The firm supervised the contracting, architecture, and rentals of the Center. John R. Todd was credited with the largest share of this direction.

Dr. J. M. Todd, whose home in New York was at 42 Fifth Avenue, was a trustee of Beloit College, to which he often contributed. He also aided Boothbay Harbor, Maine, where he had his summer home. He equipped the town office there at his own expense. Dr. Todd's interest in Beloit College became evident in 1921, when he made large gifts for scientific equipment. When plans were discussed for construction of men's dormitories on the campus, he gave generously, both of his engineering skill and of his finances. He also provided the department of science with modern equipment and reference books. He was responsible for rebuilding and re-equipping the departments of chemistry, physics, mathematics, and geology.

Dr. Todd practiced medicine in Minnesota for ten years, and his success in this field was unqualified. For forty years and with the same success, his energies and his skills were devoted to constructing a number of the largest projects in the largest city of our land. As with James J. Hill, when Hill had finished his Great Northern Railroad, Dr. Todd might justly have said, "I have put my

mark on the face of the earth and they cannot rub it out." Dr. Todd died at his Boothbay Harbor home in January, 1939, at the age of eighty-one.

Dr. Gaffney came to Hartland in 1890. According to old residents there, he was not a doctor. Records show that he operated a meat market in 1890-91 and then rented the market and learned telegraphy. His next venture was the raising of trotting horses. In 1893 he was at Independence, Iowa.

Dr. ——— Lang located at Hartland in 1890. In 1991 he moved to New Richland, Waseca, County, but came to Hartland every Thursday.

Dr. John Watson, a graduate of the Medical College of Utica, New York, came from Minneapolis and located at Alden in 1892. He was at that time about sixty years of age. He did not remain long at Alden, but moved to Mountain Lake and from there returned to Minneapolis. He married a Miss Heinke of Minneapolis.

Dr. Merton L. Head was born at Albion, Wisconsin, December 14, 1867. Following his boyhood country schooling, he studied at Albion Academy and later taught country school. He matriculated at Rush Medical College and in 1894 graduated from there and went directly to Hartland to begin the practice of medicine. In 1896 he married Margit Torkildson of Hartland and to this union nine children were born. His wife was killed in an automobile accident in 1931, and in 1938 Dr. Head married Mrs. Elizabeth Stieler. In 1911, on advice of physicians at Mayo Clinic, Dr. Head sold his practice at Hartland. He moved to a farm two miles south of Albert Lea and became an ardent dairyman and a breeder of Jersey cattle, continuing a successful business until the time of his marriage in 1938, when he retired. He died at Albert Lea, December 16, 1941, of coronary thrombosis, aged seventy-four.

Dr. Head was a fine gentleman and a devoted husband and father. He gave unstintingly of himself in his large but arduous practice. His entire span of medical practice was in the horse-and-buggy days, and if one could enlarge on some of the details of his daily calls through winter's storms and springtime's mud, episodes would be revealed that would match any on record for hardships and endurance. He was admired and loved by his patients, fellow townsmen, and all with whom he came in contact.

Dr. William E. Todd was born April 26, 1861, at Willow Creek, Wisconsin, where his early schooling began. From 1869, his father held pastorates at Winnebago City, Granite Falls, Wabasha, Albert Lea, and finally at Altamont and Independence, Kansas, where he served until 1888. William graduated from Emporia College with the B.A. degree in 1886. He graduated from Northwestern University Medical School in 1890; and after his hospital internship, he took up practice in the logging and mining region about Neaunee, in the upper peninsula of Michigan. He married Maud Augusta Roller of Altamont, Kansas, in November, 1890, and then went to Madison, Minnesota, where he bought his brother J. M. Todd's practice, house, goods, and horses and continued there until 1895, when he came to Albert Lea. He practiced here with his brother, assisting him in the work in his new hospital until his brother went to New York City in 1897. He continued in a successful private practice here until 1912, when he moved to Hagerstown, Maryland, where his aging parents lived. He continued an interesting and successful private practice at Hagerstown, but being a true westerner, it took him a little time to adjust himself to the customs of the East. He attended courses in medicine at Johns Hopkins Medical School

and continued practice until his death. He was a true pioneer, a great reader, was interested in art and music, and loved humanity, particularly children. He voted the Republican ticket and was a delegate to its state convention in 1888. He was affiliated with the Knights of Pythias and the Order of Odd Fellows and attended the Presbyterian Church. He did a great deal for charities and was a poor collector. He drove fast horses and loved to hunt and fish. He died at Hagerstown in 1926, aged sixty-five. He had two children: Gertrude Elizabeth, who was born April 20, 1892, and graduated with the B.A. degree from Gaucher College, Baltimore, in 1915; and James Roller Todd, who was born May 15, 1894, graduated from Mercersburg Academy in 1915, and studied at the University of Virginia two years when he enlisted in aviation in World War I.

Dr. Henrik Nissen was born April 22, 1864, at Mahlseven (County of Tromso) Norway. He attended a well-known private school for boys in Oslo, and passed his entrance examination to the University of Oslo with distinction, at the age of eighteen. A year later, he entered upon his medical course at the same university. His degree in medicine was granted in 1888.

His later training consisted of postgraduate work in eye, ear, nose, and throat in New York and Chicago in 1893, and in Berlin and Vienna in 1897. He practiced three years at LaCrosse, Wisconsin, where he located when he came to America, and in 1892, he moved to Albert Lea where he soon established a good general practice. He later built a large building for hospital purposes, with a drug store on the ground floor. This building, known as the Nissen Block, is now taken over by a large mercantile company. He served on the Minnesota State Board of Health with Dr. Charles Mayo and Dr. Peter Hewitt, secretary, in 1895 and 1896. After his return from Europe in 1897 Dr. Nissen located in Minneapolis where he earned a splendid reputation as a specialist in eye, ear, nose, and throat.

Dr. Nissen was a lineal descendant of Hans Egede (1708-1789), recorded in history as "Greenland's Apostle" for his pioneer work as a missionary among the Eskimos in Greenland. Both his grandparents were doctors, as was his father's brother, Dr. Oscar Nissen. His father, Adam Vilhardt Glahm Nissen, born in 1837, died at age twenty-nine, having served as forester and agriculturalist in north Norway. His mother, Martha Elizabeth Istad, was born in Farsund, Norway. Of that marriage, only her son Henrik survived her. Dr. Nissen married his cousin, Fayette Pauline Egede Nissen, at LaCrosse, Wisconsin, in May, 1889. To this union six children were born: Arvid Egede Nissen, Upper Darby, Pennsylvania, metallurgist; Dagny Egede Nissen, who died in 1938, having served five years as librarian in the American Library in Paris, and as hostess for the Enlisted Men's Club at Ft. Snelling; Henrik Egede Nissen, graduate of the Minnesota Agricultural School, served in the U. S. Marine Corps, 1917-1919; Ingrid Egede Nissen (Mrs. Cooper Francis), Greenwich, Connecticut; Sophie Elizabeth Nissen, assistant professor in romance languages at the University of Minnesota; Bergelot Egede Nissen (Mrs. Robert Burgess, Jr.), New York City.

Dr. Nissen was a gifted gentleman, well built, slender, moving with easy grace, fond of nature and interested in botany and zoology. In all, he was a fine companion, of even disposition, lively, fun-loving, and congenial. He left Albert Lea because he wanted his six children to be able to live at home while they attended the university. His country calls, which came to him, as well as the other doctors, at all hours and in all weather conditions, were often long and strenuous. He kept four horses and a stable boy who usually drove for him.

During the six years that he practiced here he found his full share of Freeborn County mud both from underfoot and from the whirling wheels, and had narrow escapes from runaways and violent storms. He rode horseback for exercise and pleasure, and together with his wife, would often walk the five miles around Fountain Lake on summer evenings. His favorite pastime was to listen to his wife play the piano and sing his favorite songs, or to play chess. In season, he enjoyed duck hunting with friends.

In 1905 he took a trip to Ft. Francis, Canada, and from there he visited by canoe some of the lovely islands dotting Rainy Lake where he found their rock-bound shores appealing. On one of these he built a substantial winter home, and when he found his health failing about four years before his death, he retired from active practice and spent most of his time in this home. In the winter of 1935-1936 he realized that his days were numbered and returned to his home in Minneapolis. He died May 7, 1936 (Obituary, *Minneapolis Journal,* May 8, 1936).

Dr. William L. Palmer, the fourth son and the youngest of nine children of the Rev. and Mrs. Daniel R. Palmer, was born on the family farm near Shellrock (now Glenville), Minnesota, September 22, 1867. The family came originally from England. Zachary Palmer, the son of a minister and the progenitor of this branch of the family, settled in New England in an early day. He had four sons of whom the oldest was the Rev. Daniel H. Palmer, the father of the subject of this sketch, and five daughters. The youngest son of Zachary Palmer, Frank W., took up newspaper work at an early age. He was co-founder of a daily newspaper at Des Moines, Iowa, and later co-founder of the *Chicago Inter-Ocean.* He served as postmaster of the city of Chicago, and next assumed the office of public printer during the administration of Benjamin Harrison and Grover Cleveland.

The Rev. Daniel H. Palmer, after graduating from the Baptist Theological Seminary, served two years as colporteur before his ordination into the ministry. He married Mary Caroline Buck of New York. They served congregations in and around Argyle, LaFayette County, Wisconsin, until 1863, when they moved to Freeborn County and filed on a homestead near Glenville. The Rev. Daniel H. Palmer founded the Baptist church at Albert Lea, the one at Northwood, Iowa, and organized a class at Glenville. He held services at Northwood and at Albert Lea for years, either walking from Glenville or driving a yoke of young oxen, to meet his appointments on alternate Sundays. Once, with a companion, he had a narrow escape on a trip to Northwood by losing the trail in a Minnesota blizzard. During the week he taught in the old "Green" school, and when he was called away his wife would take his place in the school room. Owing to bad weather and lack of roads, the Palmer children were taught at home until they were old enough to face the hardships of walking the necessary miles to school.

When the Rev. D. H. Palmer died in 1872, at the age of forty-eight, the twenty-one year old son, Morris, assumed the care of the homestead and family until his death in 1882. The daughter, Sarah E. Palmer, taught in the high schools of the state after her graduation from the University of Minnesota. In 1898 she went to Adyar, India, where she taught in schools of higher learning for more than forty years. She was active in school work and literary circles until she died there in 1945 at the age of ninety-one years. Daniel S. Palmer, the second son, graduated from the medical school at Cincinnati, Ohio. He practiced medicine for many years at Holdrege, Nebraska. He is survived by one daughter, Mrs. Ruth Schmilkin, now connected with the state university at Lincoln, Nebraska.

Mary Alma Palmer married James S. Casper, and they are survived by one son, Guy. Clara Jane Palmer married Benjamin Shafer of Mankato, and they are sur-

vived by one daughter, Mrs. Lottie M. Owens of Taft, California. Martha F. Palmer married Arthur W. Trow of Glenville, who for many years lectured on dairying with the Minnesota State Institute. They are survived by two sons: Clinton F. of Ontario, Oregon, and A. Palmer of Seattle, Washington. Frank H. Palmer studied theology and was of the fourth generation to become an ordained minister. He married Clara Marving of Glenville. Both died early, leaving no living descendants. Viola N. Palmer married J. Bartlett of Glenville. Their only son died in childhood. Seven of the Palmer sons and daughters taught in the old "Green" school in the early days, and each of the seven married a school teacher.

Dr. W. L. Palmer was five years old when his father died. After his brother Morris' death he became, at the age of fifteen years, his mother's chief support and companion until her death. Like the other children, he received his schooling at home until he was old enough and rugged enough to venture the long trail to the old "Green" school house. After finishing rural schools he attended the Albert Lea High School. Very early in life he chose the medical profession as his career, and after teaching in rural schools of Freeborn County for two years, he began the struggle to achieve his cherished goal. He went to Wisconsin, where he engaged in the milling business and became head miller in a 150-barrel mill. He continued work here for four years but also found time to study medicine under a preceptor. During these busy years he studied pharmacy and passed the Wisconsin State Board as an assistant pharmacist. He matriculated at Rush Medical College in 1893 and graduated in 1896, with the distinction of being elected president of his class. He began his practice at Glenville the same year, serving the surrounding community for ten years through horse-and-buggy days. He kept three span of the best driving horses obtainable, and two drivers because often his only sleep was during travel between cases. He located at Albert Lea in 1906, where for several years the leading surgeons had been Dr. Frank A. Blackmer and Dr. Henrik Nissen, and the leading physicians Dr. A. C. Wedge and Dr. J. P. von Berg. His ability and sincerity were soon recognized, and he was received with friendly cooperation.

Dr. W. L., as he is affectionately known throughout this community, because of his skill, personality, and loyalty, soon acquired a wide reputation as a surgeon. His unfailing promptness in responding to calls from patients and from doctors needing assistance, won for him life-long friendships of both doctors and patients throughout this and adjoining counties in Minnesota and Iowa. One instance of this promptness and loyalty to a doctor friend occurred on a bitterly cold and stormy December midnight thirty years ago. The patient, with a ruptured tubal pregnancy, was, by the very liberal hypodermic use of the "king" of all medicines, bundled and placed from the floor onto a barn door and transported four miles on top of an old open, two-seated Buick. When the anxious doctor and his patient arrived, Dr. W. L. had already checked in at the little four-bed cross-road hospital after his twenty-eight mile drive over drifting snow-covered roads. But aside from a few sponges, there were no sterile goods at hand. So the old wash-boiler was filled with towels, gowns, and sheets and W. L. stripped to his waist, draped the patient and himself with wet sheets, towels, and gowns, and finished the bloody job successfully. But the husband in this case had just had a sale and was to move across the border the next day. He was told that the fee would be about one-half the price of a decent funeral. The village banker was hustled out of bed, the fee was paid, and W. L. was on his way back to Albert Lea in time to meet his appointments. He was built for service, being six feet tall, straight as a ramrod, weighing 235 pounds, and always willing. Now retired at age of eighty-one, he prefers to go to his north woods cabin and do his fishing through the ice.

After locating at Albert Lea he took a very active part in founding the Naeve Hospital and its staff, of which he was elected the first president. He specialized in surgery, obtained degrees from New York Polyclinic and Chicago College of Surgery, and attended European clinics. He is a member of the American College of Surgeons, the AMA, and the Minnesota State and Freeborn County Medical Societies. During World War I he served as captain in the Medical Corps, 1917-1918. In 1889 he married Ida May Trow. His only child, a son, Dr. C. F. Palmer, a graduate of Rush Medical College, after serving internships in the Presbyterian and Washington Boulevard Hospitals in Chicago, joined his father in medical practice in 1922. This partnership was expanded to include four more members and became the Albert Lea Medical and Surgical Center.

After having served the community for fifty years, Dr. William L. Palmer retired from active practice in 1946, and since then has given his entire attention to his farms and extensive general investments.

Dr. Olav E. Rodli was born in Nordland, Norway, December 8, 1867, and received his early schooling there. He entered the preparatory school at Oslo, received his B.A. degree from the University of Oslo, and graduated from the medical department of that university in 1892. He came to Albert Lea in 1896 and began practice as assistant to Dr. Henrik Nissen. After Dr. Nissen moved to Minneapolis in 1897, he continued private practice until 1919, when he retired to devote his time to managing the family farms. He married Nora Guldbrandson and with her had four children: Gilbert, Roal, Ruth, and David. His wife died in 1918. Dr. Rodli left Albert Lea in 1931 and is now residing with a son who lives in Pennsylvania.

Dr. George H. Briggs was born at Keene, New Hampshire, January 30, 1827. He practiced at Keene but where he graduated in medicine is not known. He moved to Delavan, Wisconsin, and practiced there until he enlisted for service in the Civil War and served as surgeon in a Wisconsin regiment. After the war he practiced for two years at Delavan and then established a drug store there. He came to Albert Lea in 1892, established a drug store and continued in that business until his death December 12, 1907. His son, Charles Briggs, took over the drug store after his father's death and continued the business for years until his death.

Dr. Briggs never practiced medicine in Freeborn County. A kind, gentle, and deeply religious man, he was highly esteemed as a citizen, neighbor, and friend. He had six children, of whom two died at an early age; a daughter, Helen, who became a music teacher at Macalester College; and a son who became an officer in the Salvation Army.

(To be continued in March issue.)

President's Letter

IS IT WORTH TWENTY-FIVE DOLLARS TO YOU?

At the Interim Session of the House of Delegates of the AMA, held in St. Louis November 30—December 1, 1948, a resolution was unanimously adopted to authorize the Board of Trustees to levy an assessment of twenty-five dollars on the members of the AMA. These funds are to be utilized to form a national planning committee "to guide a nationwide plan of education on the progress of American medicine, the importance of conservation of health and the advantages of the American system in securing a wide distribution of high quality medical care." These funds will also aid in enlarging and increasing the activities of the office of the AMA in Washington, D. C.

Since the first social insurance laws were passed by congress in 1911, continuous attempts have been made by the socializers in the federal government to expand this program. This was climaxed by the introduction of the Wagner-Murray-Dingell bill in 1943 and again in 1945. Neither of these bills came out of the committee rooms.

On December 10, 1946, Thomas Perron, surgeon general of the U. S. Public Health Service, advised his field men that the executive agencies of the government had been instructed by President Truman to assist in carrying out the proposed National Health program. The U. S. Public Health Service then launched a series of so-called health workshops throughout the country, including Minnesota, to develop pressure groups for the insurance program and generating public sentiment in favor of socialized medicine. About 45,000 federal employes were so engaged and about $75,000,000 of the taxpayers' money was expended. It is absolutely contrary to law to use federal funds to influence legislation pending before congress. The Harness investigating committee reported (House Report 786, 80th congress) this to the U. S. Department of Justice, with the request that the Attorney General at once initiate proceedings to stop this illegal expenditure of the taxpayers' money.

I am submitting this information simply to emphasize the powerful influences at work to force socialized medicine on the American public. In September, 1948, Oscar R. Ewing, federal security administrator, at the request of the President, prepared a report, 186 pages long, entitled, "The Nation's Health, a Ten-Year Program." This report should be carefully studied by everyone interested in socialized medicine. In it are many misleading statements which cannot be substantiated scientifically.

In this report Mr. Ewing furthermore suggests the free choice of physicians, retaining the confidential physician-patient relationship, et cetera, the professional freedom of accepting or rejecting patients, the right to choose the method of payment for services rendered. Doctors, he states, could expect to earn better incomes under an insurance system than they do now.

Personally, I do not believe that a Compulsory Health Insurance law would ever contain these provisions, but that the ultimate outcome would be a panel system on a salary basis for physicians. A recent newspaper release stated that the new compulsory health insurance bill will be very similar to the two previous Wagner-Murray-Dingell bills. These definitely included a panel system, or salary basis, for physicians and *no* free choice of physicians.

History has demonstrated repeatedly what socialized medicine has accomplished in every country where it has been established: a deterioration in the quality of medical practice and a decrease in scientific progress. Great Britain, with its extensive socialized program in all fields, is the most recent example of how this program affects the individual, the public and the nation.

With a President and a Congress favorable to national compulsory health insurance, the medical profession of this country is confronted with the most critical period in its entire history. The American public is not as much interested in the medical profession as in its own personal welfare. Therefore, along with the educational program suggested by the AMA it is fully as vital to have the American public realize that socialized medicine will:

1. Affect the happiness of every family, by depriving its members of the free choice of physicians;

2. Affect the health of every family, because medical service will be inferior;

3. Affect the income of every family, because *all* earned income up to $4,800 will be taxed at least four per cent, besides additional federal tax to make up the deficit (This program will incur an annual federal expense of 5 to 10 billion dollars for the American taxpayer. The delusion that this program will furnish *free* medical care must be corrected.);

4. And, most important, socialized medicine is merely a stepping stone to further complete industrial socialization of our country.

Do you want the government to take over your business?

Full-hearted co-operation will prevent this.

President, Minnesota State Medical Association

Editorial

Carl B. Drake, M.D., *Editor;* George Earl, M.D., Henry L. Ulrich, M.D., *Associate Editors*

D. P. PHYSICIANS

CONSIDERABLE newspaper publicity has been given to the disappointment of two physicians (displaced persons) who had come to this country from Europe, one to a locality in Wisconsin and another to Minnesota, expecting to practice medicine in these new locations. The unfortunate plight of most D. P.'s is deplorable, and the disappointment of these two physicians naturally appeals to the sympathy of true Americans. The unfortunate occurrence has led certain newspapers to play it up as a sob story and point the finger of blame at the medical profession—to the undoubted delight of those unfriendly to the profession.

Each state has its Board of Medical Examiners composed of physicians whose function it is to pass on the qualifications of those who are licensed to practice medicine. This is to assure that only those who have had proper training in medicine and are of sound character obtain licenses to practice the healing art. This is primarily for the protection of the public against the incompetent and dishonest doctor. We do not know of any State Examining Board that has deliberately refused to license a physician able to pass the required examinations simply to prevent competition. By and large the law of supply and demand is allowed to control the number of licensed physicians in any state.

Laws regarding the licensing of physicians differ in the different states. In some states licensing is controlled by regulations passed by the Boards of Medical Examiners. Some states require full citizenship; others require first papers; some require a year of internship in a hospital within the state; many require credentials as to medical education which are often impossible to obtain. Our boards have no way of ascertaining the worth of some credentials which have been presented by D. P.'s and in some instances those presented have proven bogus.

Medical education in certain European countries has been in a deplorable state during the past decade. Under the Nazi regime, numbers rather than quality was the objective. How can a board judge the qualifications of a physician trained in Russia? The same applies to Poland. Austrian medicine, which not so long ago represented the acme of medical training, has had no opportunity to keep abreast of the outstanding advances in therapeutics such as the use of the antibiotics.

It is said that some 6,000 D. P. physicians have entered the United States up to 1942, 3,500 of whom have been licensed. The greatest influx has been in the eastern states, notably New York and Massachusetts. Many State Boards have considered the state of D. P. physicians with much sympathy and have permitted applicants to take and retake examinations repeatedly. Actually it is much easier for a D. P. physician to obtain a license to practice in this country than for an American physician to be licensed in most foreign countries.

The first article in this issue of Minnesota Medicine contains informative material prepared by the Minnesota State Board of Medical Examiners and should be read by members so they may become posted on the subject of the licensing of displaced physicians in Minnesota. It shows that the Board has acted within its rights, as established by law, in the passing of regulations. In requiring citizenship before a physician is allowed to take examinations for licensure, the Board is not exceeding the requirements for lawyers, dentists and pharmacists. It is on this requirement that some have felt that the Board has been too exacting, and that the taking out of first citizenship papers and thus signifying the intention of becoming citizens should be sufficient. The possession of medical knowledge sufficient to pass the examinations and a good moral character should be the prime requisites for licensure. The latter may well be more difficult to determine than the former.

That 99 per cent of those examined in the past twenty-one years have passed the examinations and have been licensed does not indicate that the Board's activities have been directed towards limiting competition by unduly restricting the issuance

of licenses, a view that has been inferred by recent newspaper articles. The registration of one physician for every 700 people in the state does not suggest a great dearth of doctors in Minnesota. The problem, if any, is rather one of distribution than numbers.

Before this appears in print, the Board will have had another meeting. What action, if any, will be taken to ease the plight of D. P. physicians will have been made public. The Board's function, that only physicians with proper training and good moral character be licensed to practice, should not be interfered with by outside pressure.

INFANT MORTALITY

THE article on Minnesota's Maternal and Child Health Program by Dr. A. B. Rosenfield, Director of the Division of Maternal and Child Health of the Minnesota Department of Health, which appears in this issue reveals some facts which are not generally appreciated.

The statement that there are more deaths in the first year of life than in the age group of two to thirty-five, inclusive, is startling. Although infant mortality in Minnesota has been reduced from 70 per 1000 live births in 1915 to 28.6 in 1947, the first year of life still constitutes a hurdle for the newborn. This satisfying decrease in infant mortality has been largely affected in infants in the age period of one month to one year, which indicates that the first thirty days of life are the most hazardous.

The author's analysis of the deaths in the first month of life indicates that half are due to prematurity, an obstetrical problem. That prematurity is ninth in the list of causes of death indicates the importance of the problem. The 16.3 per cent due to birth injuries merits an analysis with the expectation of a reduction. Until we know more about the cause of congenital malformation, the 15.4 per cent due to this cause cannot be bettered.

Another point which the author emphasizes is that only 50 per cent of Minnesota children are fully immunized before entering school. The fact that twenty-five deaths from whooping cough during the first year of life occurred in 1947 and over a third of the twenty deaths from diphtheria occurred under the age of five, indicates the advisability of carrying out the immunization program against smallpox, diphtheria, whooping cough and tetanus in the first year of life.

ANTIVIVISECTIONISTS

ANTIVIVISECTIONISTS for the most part are individuals who have allowed sentimentality to outweigh their judgment. Although some of the leaders in the antivivisection society may have ulterior motives, such as personal financial gain, or possess the type of minds that are "agin" everything, it is undoubtedly true that the majority of members are swayed by the feeling that it is not right to make animals, and especially the dog, who is known as man's best friend, suffer. They do not have the full picture as to the important part played by animals in medical progress.

The public does not know the part played by the frog, guinea pig, rabbit, cat, dog and horse in medical progress. The marvelous advance in our knowledge of physiology, surgery and therapeutics would not have been possible without the experimental use of animals. The large-scale production of diphtheria antitoxin would not be possible without the use of the horse. The successful treatment of rabies utilizes the rabbit. The development of insulin would not have been possible without the use of the dog. The marvelous advances in surgery of the blood vessels, heart, lung, stomach and intestines would not have been possible were it not for trials on animals. The sulfa drugs and the new biotics, such as penicillin and streptomycin, had to be first tried out on animals. These are only some of the examples of the service rendered humanity by animal experimentation. Certainly no one could advocate experimentation, à la Hitler, on human beings.

Proponents of antivivisection do not mention the medical progress which has resulted from the experimental use of animals. They do not mention that all experimentation on animals is supervised in medical schools, for the most part, and that pain is largely minimized by anesthesia and narcotics, and that animals sent to dog pounds are uselessly slaughtered. To be consistent, they should pledge themselves never to use any therapeutic measure which has resulted from animal experimentation—insulin, liver extracts, antitoxins, penicillin, et cetera—to become vegetarians, refuse to wear fur coats and feathers.

The crusading activities of antivivisectionists have been on the increase in recent years and have acquired an estimated 10 per cent of the population in society membership. Their activities in attempting to pass legislation which would

throttle medical research have necessitated expenditures of thousands of dollars in thwarting them.

The attitude of the medical scientists in the past has been one of non-resistance, except when attempts at legislation have gone too far.

At a meeting of the Association of American Medical Colleges, held in Detroit in 1944, a committee was appointed to formulate a plan to build up public understanding and support for experimental research. As a result, in 1945 the National Society for Medical Research was founded to encourage and advance research in biology, medicine, dentistry, pharmacy and veterinary medicine, to disseminate knowledge regarding the necessity, the humane character and accomplishments of animal experimentation, and to foster research leading to prevention, control and cure of diseases in man and animals.

It was realized that there was need for a complete change of policy on the part of science from one of passivity, which meant the avoidance of even the mention of the use of animals in the interests of science, to a definitely aggressive policy, which meant the publicizing of the part played by animal experimentation. There must be an adequate and legally protected source for animals essential for experimentation. Legal action must be taken to counteract the obstructive activities of the antivivisectionists.

As a result, some 225 organizations are now supporting this new National Society for Medical Research. The society carries on a publicity campaign to acquaint the public with the true facts about the part played by animal experimentation in medical research. Newspapers, the leading lay magazines, and the radio are all being utilized. Newspapers, except for the Hearst-owned ones and the formerly Hearst-owned *Washington Times-Herald,* for the most part, have been cooperative in presenting the true picture. In the past three years, there has been a marked increase in the percentage of favorable over unfavorable newspaper articles published.

The National Society for Medical Research is a federation of scientific and civic societies formed to supply the facts about animal experimentation to the public in order to allow medical science to advance unhindered by misguided obstructionists. Members of the medical profession, as well as scientific groups, may lend their support by sending contributions to the Society at 25 East Washington Street, Chicago 2, Illinois.

RETIREMENT OFFERED MEDICAL RESERVE CORPS OFFICERS

COLONEL ROLAND S. HENDERSON, USA
Minneapolis, Minnesota

There are few members of the medical profession today who are unaware of the urgent need for their services by the Army Medical Department. As the Armed Forces expand, there has been a corresponding increase in the amount of medical services to be rendered. The Selective Service Act of 1948 provides that "no person shall be inducted until adequate provision shall have been made for medical care." The Services must meet that requirement. The Medical Department must continue to provide that medical care. To assist it in this ever-expanding task, the Medical Department has found it necessary to call for volunteers from doctors, dentists, and nurses in civilian practice.

In seeking to reinforce its professional staff, the Army has set up aggressive programs for those specialists wishing to make the military service a career, and for those choosing to assume a standby status as Reserve Officers.

Current regulations provide that commissions in the Officers Reserve Corps may be granted to doctors, dentists, and nurses who have served honorably in the Army during World War II, are able to meet the minimum physical requirements, and who have not attained their 60th birthday.

However, appointments are not limited to those with prior military service. The Department of the Army in its Circular 210, 1948, authorizes commissioning of doctors, dentists, and nurses without prior military service, provided they are licensed to practice their particular profession, can meet certain age requirements, and are physically qualified.

In any event, specialists from Minnesota may apply for their Reserve commissions through the office of the Minnesota Senior Army Instructor for the Organized Reserves, located in Room 310, U. S. Federal Office Building, Minneapolis 1, or at the nearest Organized Reserve Office.

Reservists are credited with one point per day for each day of active duty training or extended active duty, in which instance they may accumulate and receive credit for more than the 60-point maximum mentioned above.

Every year of service as a member of a reserve component prior to the enactment of the retirement act last summer is deemed to be a year of satisfactory Federal service. This is not to be construed as meaning that newly commissioned officers without prior military service are ineligible for the provisions of the Retirement Act.

To clarify the manner in which a Reserve Officer computes his retirement pay, the following example is given with the suppositions indicated:

The Reservist concerned was born in 1910 and joined

Colonel Henderson is Senior Army Instructor for the Organized Reserve Corps in Minnesota.

the Reserve Corps in 1935. He went into active Federal service December 1, 1941, and was separated December 1, 1946 (five years). He maintained a satisfactory status in the Reserves until his sixtieth birthday, 1970, at which time he was retired in the grade of Colonel.

1935 to 1941—6 years multiplied by 50 points equals (Each year of service as a member of Reserves prior to enactment of Act is deemed a year of satisfactory service for which 50 points is authorized)	300 points
1941 to 1946—5 years (active duty) multiplied by 360 equals.....(1 point for each day of active Federal service)	1,800 points

In the 24-year period, 1946 to 1970, he received retirement credit for participation in the Reserve program as follows:

He spent two years on extended active duty—360 points (1 point per day of active duty) x 2 years equals.....	720 points
One year he attended 30 authorized drill periods, and was able to attend 14 days active duty training at summer camp—15 points (for membership in reserves) plus 30 points (for attending 30 drill periods) plus 14 points (one for each day at summer camp) equals	59 points
The remaining 21 years he was able to accumulate the minimum of 50 required points per year; 21 x 50 equals.....	1,050 points
TOTAL	3,929 points

The total points divided by 360 days equal 10.9 years —the number of years creditable for retirement purposes.

$6,600.00	(Annual pay for Colonel, 30 years' service)
x .025	(Act provides that retirement pay will be paid at an annual rate equal to 2.5 per cent of the active duty annual base and longevity pay which the applicant would receive if on active duty)
$ 165.00	
x 10.9	(Years creditable for retirement)
$1,798.50	(Annual retirement pay he would receive upon attaining his sixtieth birthday.)

Newly commissioned officers have one of two alternatives following their appointment. They may volunteer for extended active duty for a period of one, two, or three years with the Army Medical Department. During the time for which they are selected, they are on full time duty status with the military service, and receive the pay and allowances of Regular Army Officers of equal rank, plus the $100 a month pay increase given to physicians and dentists who volunteer for active service.

Those not volunteering for active service with the Army may limit themselves to inactive duty training by becoming members of one of the several Medical Reserve units organized throughout Minnesota.*

Whichever the course decided upon, there are worthwhile gains for those who keep their status in the Reserve program active.

A Retirement Act passed by Congress last summer provides that those Reservists who accumulate an aggregate of at least twenty years of satisfactory Federal service as officers, warrant officers, flight officers, or enlisted persons in either the Army of the United States or the Air Force, including the reserve components thereof, and also the federally recognized National Guard prior to 1933, will be granted retired pay when they reach their sixtieth birthday. Those who were members of the reserves on or prior to August 15, 1945, must have had active service in either World War I or World War II. In order for a year to be counted as a year of satisfactory Federal service, the Reservist must have earned at least 50 points for that particular period. Fifteen of these points are automatically awarded for membership in a reserve component. The remaining required points are earned at the rate of one point for attendance at each authorized drill period, or other period of equivalent instruction. However, not more than 60 points may be credited for retirement purposes in any one year for inactive status training.

*Medical Reserve units in Minnesota include the 368th Medical Laboratory, the 364th Medical General Laboratory, 473d Medical Collecting Company, 401st Medical Base Depot Company, and the 415th Malaria Control Detachment, all of Minneapolis; the 804th Medical Hospital Center, 110th General Hospital, 803d Station Hospital, 900th Mobile Army Surgical Hospital, and the 421st Malaria Survey Detachment, all of Saint Paul, and the 467th Medical Collecting Company, with station in Brainerd.

*See note at end of article.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

NEW VERSE ADDED TO SOCIALISM'S OLD REFRAIN

Proponents of the Wagner-Murray-Dingell Bill, or variations thereof, know that, barring immediate popular acclaim, the lyrics of their national health anthem will be somewhat wearisome, if not downright unacceptable to the American public by the latter part of 1949.

So what are the sponsors of this proposal, which is making frequent return trips to Congress, doing to ease the transition from bill to law?

First of all, they have made no changes, except effective dates, in the original W-M-D Bill. This, obviously, makes further hearings an improbability and should speed the proposed legislation on its way from the committee table.

Three identical bills on national health insurance were deposited in the hopper of the 81st Congress before the session was a week old. Of the three, Representative Dingell's H. R. 783 looked the most promising to the socializers, for it had been routed to the Interstate and Foreign Commerce Committee, headed by "regular" Democrat Crosser, of Ohio.

The method of paying the nation's medical costs will be incorporated in another bill, separate from W-M-D, so that the phrasing of "free medical care for everybody" and "payroll deduction" does not contradict itself so blatantly—in juxtaposed paragraphs.

But one of the most cunning strategies employed by the politicians who would governmentalize medicine is Senator Claude Pepper's (Florida) idea of wrapping up compulsory health insurance in a package of other medical legislation, most of which would be less apt to antagonize either medical or lay people. Here's what he'd include in his omnibus bill:

1. Medical research,
2. Increased federal aid to hospital construction,
3. Federal financing of medical education,
4. Federal recruitment and training of nurses,
5. Expansion of the Public Health Service,
6. Free dental care.

Declining to comment on how well he thinks his suggestion would be received, Pepper did, however, have this uplifting thought for the day: "The 81st Congress is going to make more progress in the health field than any other congress in history. We are going to show the world that we can make democracy meaningful."

That statement, on behalf of a program more socialistic in character than even the government's stringent wartime controls, is almost perfect in its irony.

Senators Murray, Wagner and McGrath, whose bill is identical to Dingell's, claim for S.5:

That it will (1) cover 85 per cent of the population, including the self-employed and their dependents, (2) guarantee to participants medical and dental services by general practitioners and specialists, hospital and home nursing care, laboratory service, x-rays, "expensive prescribed medicines," eye glasses, et cetera, (3) guarantee free choice of physician and dentist by the patient, also the right to change, (4) make optional the participation by doctors, nurses and hospitals, including organized groups of practitioners and consumer cooperatives and "every hospital that participates is guaranteed freedom from governmental supervision or control," (5) allow the method of payment from the insurance fund "to be decided by those practitioners who furnish the service," and (6) permit members of the medical profession to participate, *along with other citizens,* in administration of the plan at the local level.

If the bill passes, it will be administered through a department that will grow out of the present federal security agency. There is some doubt about the name of the new department—it will include the words "public welfare"—but there is little doubt about who will be its director.

Oscar Ewing, present federal security administrator and chief standard-bearer for compulsory health insurance, would have, as head of the new division of the cabinet, the right to appoint his undersecretaries. It was suggested some time ago that the undersecretary for health be a licensed, qualified physician, but Mr. Ewing has expressed in no uncertain terms the course of action he would take. I want good administrators, not necessarily good doctors, in my department, he has said.

Truman and Ewing and, unfortunately, a good many others, have interpreted the election results as a green light from the people, have extracted from the ballot boxes an intangible called the will of the people and feel that no time must be lost in putting into action all the re-deal features of President Truman's (not necessarily the Democratic party's) campaign promises.

If the legislation can be rushed through before the public realizes that "free medical care" in reality means a mounting deduction from paychecks (a tax, like Social Security, to be paid partly by the employe and partly by the employer), its proponents see a better chance for its passage. In the case of self-employed persons, the entire amount of the tax must be assumed by the individual. Nor does this write "paid" across the bottom of the Nation's medical care bill. Not at all. The balance will be financed through appropriations from other tax funds, funds which accrue largely through income taxes. The bill, if it is to pass, must be shunted through Congress before the public knows what to expect of government medicine: the destruction of the time-honored doctor-patient relationship, the revocation of the right to choose a physician, the necessarily lowered quality of medical care because of a multiplying volume of patients, the mass consultations, the waiting in line, the restrictions on prescribing new and expensive drugs.

Knowing all this, Ewing fears the educational work now beginning in the AMA headquarters and designed for nation-wide application. He is doing his best, along with Boas, Falk, Davis and others, to put an unsavory label on the fund being raised by the American Medical Association to carry on this public-welfare-inspired work. They know that their flimsy promises, threadbare arguments and incoherent reasoning will not stand the strain of repeated assaults by the truth.

This, then, is the time for all good doctors to come to the aid of the public. It has a right to know the truth; we have the responsibility of telling the truth.

HEALTH INSURANCE NOT ONLY MEDICAL BILL

A number of other bills with medical significance are being brought before the 81st Congress, several of a desirable nature.

Claimed by Senator Chapman, who introduced the bill, as "the surest bulwark against socialized medicine," is S. 132 which provides for federal support to help establish adequate public health units throughout the country.

Another important piece of legislation, in the field of medical research, is S. 68 and H.R. 790, identical bills calling for a one-hundred-million-dollar federal crusade against cancer. Under the provisions of the bill, world experts would be "mobilized" and their efforts co-ordinated in an unparalleled endeavor to find the cause and cure for this disease.

Also in the interests of medical research is the filing of S. 102 and H.R. 62, which would give financial support to investigation of multiple sclerosis. S. 102 is somewhat broader than H.R. 62: it adds "and related neurological diseases," thus opening the door to accelerated study of cerebral palsy and epilepsy, for example.

Amendments are being considered for the Hill-Burton Hospital Construction Act, and there are bills in the hopper which would: authorize the commissioning of x-ray technicians in the Army and Navy, place barbiturates under the federal narcotics laws, provide for the construction of VA hospitals, one in Virginia and one in southern Texas, work toward improving the diets of low-income families by making food prices proportionate to the family's income.

SOME STATE LEGISLATION GIVEN BASIC APPROVAL

A number of bills presented to the State Legislature have received tentative medical approval. Among these are: a bill to make cancer cases reportable to the State Health Department, a proposed appropriation for a mental hygiene program, prohibition of the sale of BB guns, promotion of farm safety, increased appropriations for the Minnesota State Health Department, increased salaries for doctors, especially psychia-

trists in state mental institutions, sanitary measures approved by the State Department of Health, particularly universal milk pasteurization and the control of incorrigible tuberculosis patients.

"Keep informed; discuss and rediscuss; be on your guard," warns Dr. R. F. Erickson, chairman of the Minnesota State Medical Association's Public Policy Committee, as he indicates that doctors must ever take the initiative in recommending or disapproving legislation which could affect the health of Minnesota citizens.

STATE FARM BUREAU AIRS VIEW ON SM

"Advocates of socialized medicine should be doing some serious thinking, in view of the revelations on governmental medical service released to the public last Saturday," asserted the speaker on the Minnesota Farm Bureau radio program, December 28.

"Investigators for the Hoover commission reported, in effect," the broadcast continued, "that we have socialized medicine now, in a broad and very badly administered form."

"The federal government is assuming uncalculated obligations without any understanding of their ultimate cost, the lack of the necessary professional manpower to carry them out, or their adverse effect upon the hospital system of the country," the Farm Bureau speaker quoted from the report.

DENTAL PUBLICATION DECRIES CONTROLLED CARE

The *Fortnightly Review* of the Chicago Dental Society (January 2) has a few directly aimed words to say about the issue of compulsory health insurance:

"The plan that Mr. Ewing advocates calls for a payroll tax on employes and employers sufficient to provide about three billion dollars a year. . . He claims that his plan is not contradictory to the American system and rests upon tried insurance principles. Obviously someone is trying to pull a fast one there, for the only insurance principles Americans know about are those that call for payment of premiums by the insured that are adequate to cover benefit payments based upon experience.

"Only those persons who think that government benevolence should supplant enterprise and thrift can favor exchanging the blessings of American medicine and dentistry under a free system for the compulsory health plan now in the offing."

Hennepin County Farm Woman Pleads Guilty to Abortion

Re: State of Minnesota vs. Anna Powers

On December 30, 1948, Mrs. Anna Powers, fifty-eight years of age, residing on a farm near Osseo, Minnesota, entered a plea of guilty in the District Court of Hennepin County to an information charging her with the crime of abortion. Mrs. Powers, on the same date, also pleaded guilty to an information charging her with having a prior conviction for a felony. Following a statement of the facts to the Court, Judge Levi M. Hall sentenced Mrs. Powers to a term of three years in the Women's Reformatory at Shakopee, sentence being stayed and defendant placed on probation for three years.

Mrs. Powers was arrested on November 4, 1948, following a criminal abortion performed on October 6, 1948, on a twenty-three-year-old Saint Paul divorcee. Mrs. Powers was paid the sum of $250 for the abortion which was performed by the use of a catheter. Mrs. Powers, at the time of her arrest, denied any connection with the abortion, but subsequently admitted her guilt. Mrs. Powers has a previous conviction for a similar offense in 1939. On June 1, that year, Mrs. Powers entered a plea of guilty in the District Court of Hennepin County, to an information charging her with the crime of abortion. For that offense Mrs. Powers was sentenced to a term of not to exceed four years in the Women's Reformatory at Shakopee, where she served two and one-half years of the sentence. Mrs. Powers was required to serve her sentence in that case for the reason that the patient died following the abortion. Mrs. Powers stated to the Court that the abortion she performed on October 6, 1948, was the only one done by her since her release from the Women's Reformatory.

Bath Parlor Operator Convicted of Violating Massage Law

Re: State of Minnesota vs. Minnie Walker.

On October 28, 1948, Mrs. Minnie Walker, fifty-two years of age, operator of Minnie's Bath Studio at 704 Hennepin Avenue, Minneapolis, was found guilty after a trial in the Municipal Court of Minneapolis, of violating the State Massage Law. Judge Theodore B. Knutson sentenced Mrs. Walker to pay a fine of $100 or to serve thirty days in the Minneapolis Women's Detention Home. The Court granted a stay of execution of this sentence to October 1, 1949, on condition the defendant refrain from violating any of the laws of the State of Minnesota in the future.

Mrs. Walker was arrested following an investigation by Minneapolis police officers. On October 22, 1948, Inspector Eugene Bernath of the Minneapolis Police Department assigned policewoman Mary D. Maid to go to Mrs. Walker's place of business to determine what activities were being engaged in by the defendant. It was learned that Mrs. Walker was giving steam baths followed by a massage treatment. The massage treatment consisted of manual massage followed by more massage with an electric vibrator. Mrs. Walker also used an electric belt in connection with the massage treatment. The defendant charged $2.00 per treatment or seven treatments for $13.00. The defendant does not have a massage license, and the records of the State Board of Medical Examiners disclose that Mrs. Walker was given a copy of the massage law in August, 1945. The defendant lives at 1851 Englewood Avenue, Saint Paul, Minnesota.

Minnesota Department of Health

METHEMOGLOBINEMIA IN YOUNG INFANTS

For the past two years the Minnesota Department of Health has been receiving reports from Minnesota physicians of cases of methemoglobinemia in young infants fed on formulae diluted with water from farm wells containing large amounts of nitrate nitrogen. Most cases have occurred in the southwestern part of the state. To January 1, 1949, 108 cases had been recorded, with a 10 per cent mortality. Sanitary inspections of the farm wells involved indicate poor construction and evidence of contamination in practically all the wells examined.. Nitrate nitrogen content of these water supplies varies from 36 to 500 ppm. Although it is generally accepted that no water should be used in infant feeding containing more than 10 ppm of nitrate nitrogen, and a change to a municipal water supply is advised when water contains more than that amount, chemical analyses of municipal water supplies in Minnesota show that some supplies contain 10 or more ppm of nitrate nitrogen. Interestingly enough, there has been no report of any cases of methemoglobinemia in communities having municipal water supplies. Repeated periodic nitrate determinations of affected water supplies are being carried out to determine any effect of changes in weather and seasons.

Physicians have co-operated well in reporting cases, but earlier reporting is necessary to provide methemoglobin determinations to confirm diagnosis in hospitals not equipped to make this test. Blood drawn for hemoglobin determination has a chocolate tinge when methemoglobinemia exists. Physicians who note this condition are urged to notify the State Health Department at once as soon as methemoglobinemia is suspected. Telephone GLadstone 5973, Minneapolis, collect, to A. B. Rosenfield, M.D., director, Division of Maternal and Child Health, and arrangements will be made to help you confirm the diagnosis as well as to test the suspected water supply for nitrate nitrogen. This procedure is necessary because the cyanosis usually clears up in twenty-four to forty-eight hours in mild cases and, therefore, the methemoglobin determination must be done promptly.

The principal symptoms of methemoglobinemia are a gradually increasing cyanosis, lethargy, and frequently diarrhea. While the peculiar chocolate tinge of the blood is presumptive evidence, confirmation of the diagnosis requires a methemoglobin determination of the blood. Infants under the age of two months appear to be the ones most usually affected.

The condition must be differentiated from enlarged thymus, congenital cardiac conditions, other congenital tracheal or pulmonary conditions, as well as acute pulmonary conditions and the ingestion of other toxic materials.

Ceasing to use the suspected water for the infant's formula and changing to a safe municipal supply will usually be sufficient to clear up mild cases. Oxygen has been used by many physicians. In severe cases, 1 per cent methylene blue intravenously, 1.0-2.0 mg. per kilogram, produces excellent results.

We are anxious to determine whether this condition occurs in other parts of Minnesota as well as in the southwestern area of the state. Physicians are therefore urged to report by mail the names and addresses of any possible cases that may have occurred in their practice during the past two years, so that sanitary surveys and chemical analyses of suspected water supplies may be made. We shall be glad to call on any physician who may be interested in discussing this subject.

IMMUNIZATION INFORMATION FOR TRAVELERS ABROAD

The following information is quoted from a pamphlet recently prepared by the United States Public Health Service giving information needed by persons proceeding abroad. Such persons are now required to carry certificates of immunization certified by medical health officers.

1. *United States Requirements.*—In the absence of unusual outbreaks of disease, the United States has no immunization requirements for persons leaving the United States, except as may be required for military personnel and dependents.

The Foreign Quarantine Regulations of the United States, however, require that all persons, both American citizens and nationals of other countries, prior to admission to the United States from abroad, present a certificate (see point 6 below) showing satisfactory evidence of vaccination against smallpox within three years prior to arrival or evidence of a previous attack of smallpox. Persons not presenting such proof may be subjected to penalties and required to submit to vaccination or be held under observation for fourteen days.

In the absence of smallpox at the port of departure or on board the carrier, persons are exempt from this requirement when they depart from Canada, Newfoundland, the Island of St. Pierre or Miquelon, Iceland, Greenland, the West Coast of Lower California, Cuba, the Bahama Islands, the Canal Zone, or the Bermuda Islands.

2. *Requirements of Foreign Countries.*—As a result of international and local regulations, travelers to foreign countries may be required to show proof of inoculation against smallpox, yellow fever, typhus, and cholera. These requirements depend primarily on the prevalence of the four diseases in the countries visited or traveled through prior to arrival at each port of entry. It is recommended, therefore, that persons traveling to or through the countries listed in Annex I obtain immunizations against the diseases listed for these countries.

Because of the present world-wide situation with respect to smallpox and of the United States Foreign

Quarantine Regulation, it is recommended that travelers to any foreign country be vaccinated against smallpox.

In order to avoid delays and inconveniences abroad, immunizations should be obtained before departure from the United States. For each immunization an appropriate International Certificate of Inoculation and Vaccination should be obtained (see point 6 below). This should be carried by the traveler and shown to Quarantine Officers when proof of immunization against the above listed diseases is demanded.

3. *Other Immunization Precautions.*—For protection against additional hazards incident to travel in foreign countries it is recommended that certain other immunization precautions be taken:

(a) Every person proceeding abroad should be immunized against typhoid and paratyphoid fevers.

(b) Persons whose work may present danger of accidents or piercing or crushing wounds should be immunized against tetanus.

(c) Children under fifteen years of age proceeding to any overseas area should be immunized against diphtheria. Schick test is recommended for all adults under thirty-five years of age. If the reaction is positive, immunization against diphtheria is advised.

4. *Where to Get Immunizations.*—The following persons may get free immunizations at United States Public Health Service Stations:

(a) Legal beneficiaries of the Public Health Service.

(b) United States Government officers, employes, and their dependents leaving for foreign areas when traveling under official orders.

(c) Dependents of Army, Air Force, Navy, and Marine Corps personnel traveling under official orders to foreign countries. These individuals may also be immunized at Army and Navy medical installations.

(d) Any person requiring immunization for yellow fever. The list of Public Health Service Stations administering yellow fever vaccine is attached (Annex 2).

Any traveler not covered in items 4 (a) (b) (c) or (d) above, may get immunizations (except for yellow fever) from private physicians or, in some instances, at State or local health departments.

Yellow fever vaccine cannot be obtained by private physicians and must be administered by Public Health service personnel. The nearest station for obtaining yellow fever vaccination by Minnesota citizens is the U. S. Marine Hospital, 4141 Clarendon Avenue, Chicago.

5. *Time Required for Immunizations.*—(a) Immunizations requiring International Certificate:

Smallpox: The vaccination should be obtained at least fourteen days prior to leaving the country. The reaction at the site of the vaccination should be carefully observed and recorded on the third and ninth days after vaccination. The International Certificate of Vaccination against Smallpox is valid for only three years.

Yellow fever: The inoculation should be obtained at least ten days prior to leaving the country. A single inoculation is required. The International Certificate of Inoculation against Yellow Fever becomes valid on the tenth day after date of inoculation and remains valid for four years from that date.

Note: Yellow fever vaccine should not be given concurrently with smallpox vaccine. When both of these vaccinations are to be done, it is suggested that the yellow fever vaccine be given first and that at least five days elapse before the smallpox vaccination is done.

Cholera: Inoculations should be commenced fourteen to twenty days prior to leaving the country. The standard course of inoculations consists of two doses at a seven- to ten-day interval; a third dose is advisable. It is recommended that booster doses be obtained at four- to six-month intervals as long as the danger of cholera is present. The International Certificate of Inoculation against Cholera is valid for only six months from date of last inoculation.

Typhus: Inoculations should be commenced fourteen to twenty days prior to leaving the country. The standard course of inoculations consists of two doses at a seven- to ten-day interval. A booster dose is recommended at six-month intervals as long as danger of typhus is present. The International Certificate of Inoculation against Typhus is valid for only one year from date of last inoculation.

(b) Immunizations not requiring International Certificate:

Typhoid and Paratyphoid: The standard course of inoculations is three doses at intervals of from seven to ten days. A booster dose is recommended annually and whenever the diseases are prevalent. If more than one year has elapsed since the last series of immunizations or the last booster dose, the standard course should be repeated.

Tetanus: The standard course with alum-precipitated toxoid consisting of two doses at four- to six-week intervals is preferred; with plain toxoid, three doses at three- to four-week intervals. Booster doses are recommended one year after initial series and at five-year intervals thereafter; also at time of injury.

6. *International Certificate of Inoculation and Vaccination.*—A properly executed International Certificate of Inoculation and Vaccination should be used as proof of immunization against smallpox, yellow fever, typhus, and cholera. This certificate to be valid must be certified by:

(a) A Medical Officer of the Public Health Service at any Marine Hospital, Public Health Service Relief Station, Dispensary, or Foreign Quarantine and Immigration Station, or

(b) The local health officer, if a physician, of the area in which the private physician administering the immunization practices, or by the State health officer where there is no local officer.

(c) In the case of personnel traveling under the cognizance of U. S. Navy, U. S. Army, or U. S. Air Forces,

(Continued on Page 198)

BRONCHIAL ASTHMA

"Aminophyllin has in recent years taken a definite place in the armamentarium of asthmatic medication. Physiologically it acts by relaxing the bronchial muscles. It is also extremely valuable in relieving patients of an adrenalin fastness and is less contraindicated in cases with cardiac disorders or hypertension."[1]

By relaxing the bronchial musculature, improving ventilation, increasing vital capacity and promptly reducing both intrathecal and venous pressures,

SEARLE

AMINOPHYLLIN*

exerts a favorable influence on the rate and volume of respiration in bronchial asthma as well as in paroxysmal dyspnea and Cheyne-Stokes respiration.

*Searle Aminophyllin contains at least 80% of anhydrous theophylline. G. D. Searle & Co., Chicago 80, Illinois.

SEARLE RESEARCH IN THE SERVICE OF MEDICINE

1. Mountain, G. E.: Bronchial Asthma, J. Iowa M. Soc. *35*:324 (Aug.) 1945.

immunization and certification may be done by commissioned medical officers of these services.

Persons receiving their immunization from a private physician will take the certificate to the physician who will enter the person's name, age, sex, the origin and batch number of the material used, and dates of inoculation. For smallpox vaccinations, the physician must also enter the dates of inspection of the vaccination and the result. The prospective traveler must then take the certificate to the State or local health officer for certification.

The Passport Division of the Department of State will enclose a blank certificate in the envelope with the traveler's passport. In the event the certificate is lost or more are required, additional blanks may be obtained from:

(a) The Passport Division, Department of State, Washington 25, D.C., or

(b) The Headquarters, District Offices, Marine Hospitals, and Quarantine Stations of the Public Health Service.

(c) In Minnesota, the Minnesota Department of Health, University Campus, Minneapolis.

CANCER DETECTION CLINIC

More than half of the 292 persons examined by physicians at the cancer detection clinic held in St. Cloud in December, 1948, were found to be in need of medical care. A total of 166 persons were advised to obtain further examination and treatment from their own physicians. The one-day detection clinic at St. Cloud was sponsored by the Stearns-Benton County Medical Society, the Cancer Committee of the State Medical Society, and the Minnesota Division of the American Cancer Society.

Cancerous or precancerous conditions were found in thirty-eight of the persons examined. Other conditions included seventeen cases of hypertension, thirteen cases of keratosis, five or more cases of cystocele, cervical polyp, and cervical erosion, and three or more cases of umbilical mass, hemorrhoids, lipoma of the chest, rectocele, cervical ulceration or laceration, vaginal discharge, and vaginitis.

Females examined numbered 213, males seventy-nine. Ages ranged from twenty to over seventy. There were seventeen different nationalities represented.

Annex I

Immunization Precautions.—As a result of international or local regulations, travelers may be required to show satisfactory proof of immunity to smallpox, yellow fever, typhus and cholera. Persons proceeding to or through the countries listed below should obtain the immunizations recommended for those countries and should also obtain a properly executed International Certificate of Inoculation and Vaccination which should be shown to Quarantine Officers when proof of immunization against these four diseases is demanded.

NATIONAL CANCER GRANTS

National Cancer Institute grants of $810,956 for cancer control projects and for cancer teaching in medical and dental schools have been announced by Oscar R. Ewing, Federal Security Administrator. The awards were approved by Dr. Leonard A. Scheele, Surgeon General of the Public Health Service, and had been recommended by the National Advisory Cancer Council, a group of non-government cancer experts.

Eleven grants for cancer control, totalling $202,417, went to non-federal institutions and agencies to support studies of cancer diagnostic tests, occupational cancer, tumor pathology, cancer teaching methods, and other special control projects. Grants to continue cancer teaching of undergraduates went to twenty-three medical schools and nine dental schools, and totalled $608,538.

AMERICAN BOARD OF OPHTHALMOLOGY

The American Board of Ophthalmology announces that it does not evaluate, approve, or disapprove any ophthalmic residency toward fulfilling the requirements for candidates for board examinations. Any candidate who qualifies for the board examination and completes the prerequisites as outlined in the booklet of information will be accepted. A copy of this booklet can be obtained from the Secretary of the American Board of Ophthalmology, 56 Ivie Road, Cape Cottage, Maine.

* * *

CHICAGO MEDICAL SOCIETY

The fifth Clinical Conference sponsored by the Chicago Medical Society will be held at the Palmer House, Chicago, March 1, 2, 3, and 4, 1949.

The conference comprises a four-day intensive postgraduate course for the general practitioner and will be presented by outstanding clinicians from numerous medical centers. Newer methods of diagnosis and treatment will be included in the scientific program, and scientific and technical exhibits of the highest quality will be displayed.

The registration fee of $5.00 should be sent to the Chicago Medical Society, 30 N. Michigan Avenue, Chicago 2, Illinois.

* * *

CONTINUATION COURSES

The University of Minnesota announces a continuation course in Proctology to be presented at the Center for Continuation Study for one week, April 11 through 16, 1949. The course is intended for doctors of medicine who are engaged in general practice. Emphasis will be placed upon those aspects of proctology which are of particular concern to the general physician. Presentation will be by means of lectures, discussions, motion pictures and operating room demonstrations. Enrollment will be limited to 20.

A continuation course in Physical Medicine will be presented at the Center for Continuation Study on March 28, 29 and 30, 1949. The course is intended for doctors of medicine who are engaged in general practice. The various forms of physical therapy will be discussed and the indications, contraindications, dangers, and limitations will be emphasized. Special emphasis will be placed upon the role of physical medicine in such conditions as arthritis, fractures, and various psychosomatic disturbances. Faculty for the course will include members of the staff of the University of Minnesota Medical School and the Mayo Foundation.

A continuation course in Pediatrics will be presented at the Center for Continuation Study on April 7, 8, and 9, 1949. The course is intended for doctors of medicine who are specializing in Pediatrics. The first day of the course will be devoted to problems of allergy in pediatric practice. Emphasis will be placed upon diagnosis and management of hay fever, asthma, and skin allergy. Immunological concepts will be emphasized. An evaluation of the newer drugs will also be presented. Two days of the course will be devoted to infectious diseases in pediatric practice. Subjects to be presented include common respiratory diseases, toxoplasmosis, histoplasmosis, tuberculosis, and rheumatic fever. Faculty for the course will be made up of members of the staff of the University of Minnesota, Mayo Foundation, and distinguished visiting physicians from other medical centers.

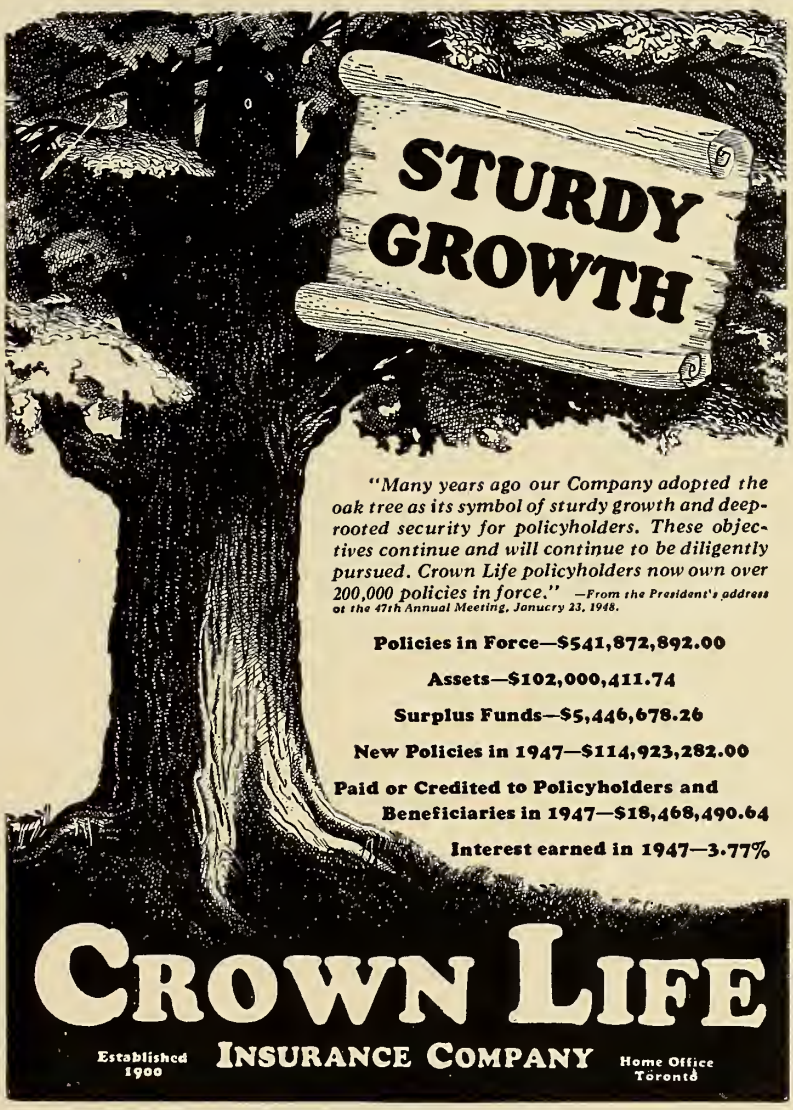
* * *

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

A meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club, Saint Paul, on January 11. Two papers were presented on the scientific program. Dr. Collin S. MacCarty, Rochester, presented his inaugural thesis on "Thoracic, Lumbar and Sacral Cordectomy." Dr. Robert Fawcett and Dr. Reynold A. Jensen, of the University of Minnesota, presented a paper on "Gasoline Addiction in a Child."

FREEBORN COUNTY SOCIETY

Re-election of Dr. S. A. Whitson, Albert Lea, as president, marked the annual meeting of the Freeborn County Medical Society in Albert Lea on December 9. Also elected to office were Dr. M. O. Nesheim, Emmons, vice president; Dr. R. A. Demo, Albert Lea, treasurer, and Dr. E. S. Palmerton, Albert Lea, secretary. Featured on the evening program were motion pictures taken by Dr. B. A. Leopard, Albert Lea, during a trip through Central America.



BLUE EARTH COUNTY SOCIETY

At the annual meeting of the Blue Earth County Medical Society, held in Mankato during the last week of December, Dr. A. A. Schmitz, Mankato, was elected

president of the organization. Other officers named at the meeting were Dr. R. W. Kearney, vice president, and Dr. O. H. Jones, secretary-treasurer, both of Mankato.

PARK REGION SOCIETY

The Park Region Medical Society held its annual meeting at Fergus Falls on December 4. The following officers were elected: Dr. H. K. Helseth, president; Dr. George C. Jacobs, president-elect; Dr. L. A. Dwinnell, vice president; Dr. Ralph Estrem, secretary, and Dr. W. O. B. Nelson, treasurer, all of Fergus Falls.

RANGE MEDICAL SOCIETY

At a meeting of the Range Medical Society in Chisholm early in January, Dr. T. A. Estrem of Hibbing was elected president of the group. Dr. Sidney Blackmore, Keewatin, was named vice president, and Dr. R. E. Hansen, Hibbing, secretary-treasurer. Talks by Dr. M. G. Gillespie and Dr. H. G. Moehring, of the Duluth Clinic, were presented during the scientific program.

ST. LOUIS COUNTY SOCIETY

At the annual meeting of the St. Louis County Medical Society in Duluth on December 8, Dr. M. H. Tibbetts, Duluth, assumed the office of president, to succeed Dr. P. S. Rudie, Duluth. Named as president-elect of the organization was Dr. L. R. Gowan, Duluth, who will serve in 1950. Other officers elected were Dr. W. F. Neff, Virginia, vice president, and Dr. K. E. Johnson, Duluth, secretary-treasurer. As part of the evening program Dr. Vernon D. E. Smith, Saint Paul, showed motion pictures of duck hunting, skiing, big game hunting and Alaskan fishing.

STEARNS-BENTON COUNTY SOCIETY

Dr. S. T. Raetz, Maple Lake, was named president of the Stearns-Benton County Medical Society at a meeting held in St. Cloud on December 16. Other officers elected were Dr. R. C. Smith, Holdingford, vice president, and Dr. J. N. Libert, St. Cloud, secretary-treasurer.

Following the election of officers, the society members attended a lecture at the St. Cloud Veterans Hospital where Dr. J. S. Cartney, Minneapolis, spoke on "Embolism of the Lungs."

WASHINGTON COUNTY MEDICAL SOCIETY

At the regular monthly meeting of the Washington County Medical Society, January 11, 1949, Dr. K. H. Pfuetze, Superintendent of the Mineral Springs Sanatorium, Cannon Falls, conducted a general discussion regarding follow-up, by private physicians, of individuals whose films in the x-ray survey indicated abnormality.

Dr. Richard A. Knudson, an associate of Dr. J. A. Poirier, Forest Lake, was elected a member of the society.

MEDICAL BROADCAST

The Minnesota Department of Health inaugurated its first regular series of radio programs on Monday, February 14. The programs will be given at 11:15 every Monday morning over Station KUOM in the Twin Cities.

Dr. Robert N. Barr, chief of the Health Department's Section of Maternal and Child Health, has taken over the KUOM radio spot left vacant by the departure of Dr. Donald A. Dukelow for a position with the American Medical Association in Chicago. Dr. Barr was introduced to his radio audience by Dr. Dukelow on the broadcast of February 14.

Dr. Barr's program subjects for the next few weeks will be:

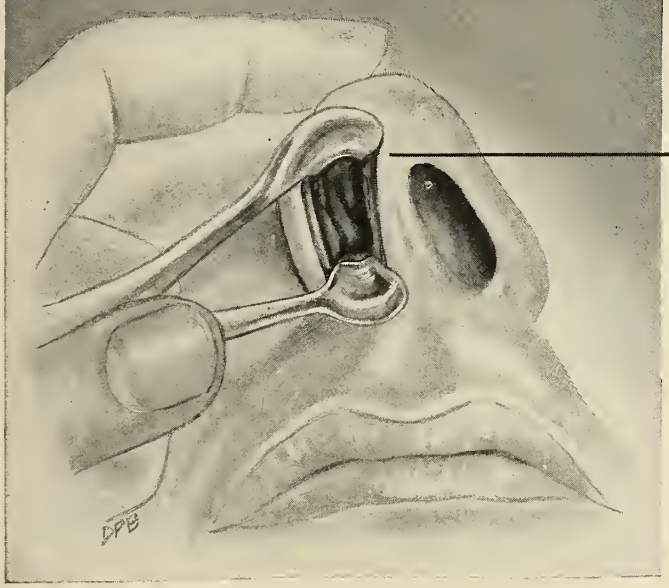
Feb. 21—What Is Mental Health?
Feb. 28—Public Health Bills in Congress.
Mar. 7—It's Your Health Department.
Mar. 14—Health Days and Health Councils
Mar. 21—Why Vital Statistics?
Mar. 28—Tracking Down Epidemics.

CASE RECORD OF ST. MARY'S HOSPITAL, DULUTH

(Continued from Page 176)

be unassociated with systemic diseases such as diabetes or tuberculosis, (2) the ulcer must be seen by esophagoscopy or at necropsy; (3) free gastric hydrochloric acid must be present; (4) the ulcer must be chronic, and (5) the symptoms must be relieved by peptic ulcer therapy and dilatation.

The complications of such ulcers are hemorrhage or perforation or both. In some reports a differentiation is made between perforation above or below the diaphragm. One such series classed all perforations above the diaphragm as fatal. The pleural and pericardial cavities, the aorta, the lungs and the mediastinum are all vulnerable to a perforation above the diaphragm. A perforation below the diaphragm usually causes peritonitis of the lesser peritoneal sac or involves the entire peritoneal cavity. In the case presented, the perforation was above the diaphragm and involved both pleural cavities, both lungs, the pericardial sac and the mediastinum, thence into the peritoneal cavity.



Questions

Dr. H. G. Moehring (Roentgenologist): Was there any opportunity for x-ray studies to identify any subdiaphragmatic effusion or accumulation?

Dr. A. J. Spang (Surgeon): Were any blood amylase studies made?

Dr. E. L. Tuohy: The answer to both questions is "no." Dr. Barron has given a masterly analysis of the sequences here shown. Students and practitioners have long been indebted to him for his teaching zeal. As he has well said, "Whether I am right or wrong in my specific deductions, I assert that the method of analysis is correct, and that is the only credit I accept."

Woman's Auxiliary

OUTSTANDING SPEAKERS AT NATIONAL AUXILIARY SESSION

Mrs. Harold Wahlquist
State Auxiliary President

The fifth annual conference of national committee chairmen, state presidents and presidents-elect was held by the Woman's Auxiliary to the American Medical Association, November 4 and 5, in Chicago. These conferences are valuable to both president and president-elect: the former benefits by being reactivated with enthusiasm for her job and by gathering many ideas and suggestions with which to supplement the work of her year; the latter, by getting her first insight into the magnitude of the work that can be done by Auxiliary members.

The conference lasted two days. Its schedule has become rather fixed after experimentation these last several years. Mrs. Luther Kice, national president, read the call to order, welcomed members and guests and presented Mrs. David Allman, president-elect and chairman of the conference. Following the election of the secretary and appointment of the Recommendations committee, the secretary called the roll, finding twenty-eight presidents, twenty presidents-elect and six standing committee chairmen present. Fourteen national officers were guests.

With preliminaries out of the way, members settled down for hours of work and study. National chairmen presented their recommendations and problems; speakers from AMA, invaluable as sources of authentic information, appeared at intervals. Relaxation came in the form of carefully planned luncheons, at which members of the executive committee of the AMA Board of Trustees were Auxiliary guests.

Toward the end of the first day, presidents began reporting, and this interchange of information alone could have made the conference worthwhile. Activities of the state units varied greatly; many specialize year after year in certain projects, with resultant perfected techniques.

Delegates had an opportunity to talk informally and to become acquainted at an evening dinner, scheduled for the first time this year. The Hawaiian Medical Society sent each member an orchid, via the president of the Hawaiian Auxiliary.

The reading of recommendations by the chairman of this committee concluded the business of the conference.

The speakers (whose talks will be summarized in a later issue) were outstanding. Fred V. Hein, Ph.D., the AMA's consultant on physical fitness at that time, spoke on "School Health Problems"; William Doscher, assistant director of public relations, AMA, "Auxiliary Public Relations"; Frank G. Dickinson, Ph.D., director of the AMA Bureau of Medical Economic Research, "Medical Economics in Relation to the Woman's Auxiliary"; Arthur Conrad, assistant administrator, National Physicians committee, "The Forces Behind the Drive for Socialized Medicine and Education"; Thomas A. Hendricks, secretary, AMA Council on Medical Care, "The Hoover Commission."

The Auxiliary was specially indebted to Dr. Louis H. Bauer, vice chairman of the AMA Board of Trustees, for his pertinent talk on the World Medical Association and the World Health Organization, which is a branch of UN, government supported, representing health organizations of twenty-nine countries. He expressed the feeling that the two organizations could complement each other and work together in harmony.

DRAFT REJECTIONS PROVE EXCELLENCE OF MEDICAL CARE

Mrs. Elmer Rusten
State Legislative Chairman

Fact-hungry United States, a nation with a commendable "prove it to me" attitude, has been struggling since World War II to engorge some pretty unpalatable statistics—figures and percentages which emerged from Selective Service operations and have been framed as an indictment of the medical profession.

In essence, the report of the propagandists for socialized medicine is that 36 per cent of all eligible young men examined by Selective Service boards was found to be physically unfit for military service.

With more twisted statistics, they have explained this huge rejection rate as resulting from the fact that one-third of the people, those in the low-income group, were more subject to sickness and unable to pay for adequate medical care.

The truth, revealed by Dr. Maurice H. Friedman's investigations, is that *only a fraction of one per cent* of total rejections could have resulted from the unavailability or the cost of medical care. Here is how his analysis whittled down the 36 per cent figure:

"Between December 7, 1941, and December 31, 1943, the draft boards selected about 10 million men for examination, and of these about 3.6 million were rejected, i.e., a rejection rate of about 36 per cent. During this period, however, 2.7 million men voluntarily enlisted in the armed forces. If these men had gone through the Selective Service examination, the total number of men examined would have been 12.7 million, and the rejection rate, 28.4 per cent."†

A full 20 per cent of these rejections was for conditions not medical—illiteracy, mental deficiency and syphilis, for example! This lowers the 28.4 per cent still further: to 22.7 per cent.

Diseases not preventable and not remediable—mental

disease, heart conditions, congenital defects, defective vision, overweight, underweight—accounted for approximately 45 per cent of the rejections, putting the figure down another notch, to 9.92 per cent. Diseases or conditions not preventable, but correctable, added up to 16 per cent of the total rejections and subtracting them from the total leaves 5.42 per cent of the rejections having possible medical care implications.

The percentage dwindles to a fraction of 1 per cent in the light of one of the most important discoveries Dr. Friedman made: one rejectee could be counted as five! In other words, a man called and rejected each time the standards were changed was counted as a separate rejection each time he appeared for examination. There were tens of thousands of such duplicate rejections, Friedman declares.

Instead of viewing the rejection figures as a condemnation of the medical care system in this country, Dr. Friedman asserts that they prove the universality and effectiveness of the system. "There were men with one hand or one leg, some with arrested cases of tuberculosis or diabetes, others with punctured ear drums or one eye. These men, though incomplete, were active, useful human beings. They were men—not corpses in graveyards due to medical inattention. One and all they were living testimony of the availability of medical care and the competency of American physicians."

BROADER AUXILIARY PROGRAM: FUNDS NEEDED

Mrs. George Penn
State Treasurer

Never before in the history of medicine has it been so important for the Woman's Auxiliary to have a progressive and forward-looking public relations program. The AMA is asking more assistance from the Auxiliary, and as a result, activities are outdistancing finances. One secretary, for example, cannot keep up with the duties assigned to her; the budget of the national president has been increased, because traveling expenses have risen and the AMA is eager for her to attend as many meetings as possible.

Fulfilling national obligations without going into debt cannot be done without additional funds. At the Board of Directors' meeting held recently in Chicago, the Corinne Keen Freeman fund had to be transferred to the checking account so that current expenses could be met.

Last June, at the annual national meeting, the House of Delegates revised the national dues from 25 cents to $1 per member, believing that every member of the Auxiliary would voluntarily subscribe 75 cents more for the important work that the Auxiliary has set out to do.

State dues remain the same—25 cents, while county auxiliaries determine individually the amount of dues necessary.

By this time county auxiliary treasurers have received their forms and membership cards, relayed to them from the national treasurer by the state treasurer. (This work is all on a volunteer basis.) County treasurers then remit all membership dues by *March 15* to the

MAY-O-LITE...and 5/1,000,000 of an inch... Prevent a "Headache"!

Do your patients complain that night driving is a "headache"? Are they confused by lights . . . lights coming at them . . . lights behind them . . . street and intersection lights . . . and neon signs of every color? Are they still blinded, even though the lights of an approaching car are lowered?

For centuries, reflected light upon the surface of spectacle lenses has been a problem to many people. Since Roger Bacon, in the 13th century, first conceived the idea of improving faulty vision by constructing a pair of spectacles from magnifying glass, surface reflection has been one of the greatest handicaps of those who wear glasses.

Now, through the development of MAY-O-LITE, these surface reflections on spectacle lenses can be up to 95 per cent eliminated! MAY-O-LITE is a special vacuum coating applied 5/millionths of an inch thick to the lense surface.

By recommending MAY-O-LITE lense coating to your patients . . . you not only save them many night-driving "headaches" but you also help minimize their eye strain and improve their image definition.

Write today for a descriptive pamphlet and a treated sample of glass.

Minneapolis 1, Minnesota

state. The national fiscal year ends March 31, at which time all dues and reports must be received by the national treasurer. It is difficult for some counties to meet this March 15 deadline, in view of the variance of county fiscal dates: in Minnesota, with twenty-eight organized auxiliaries there was a variation of 10 fiscal dates.

Last year total Auxiliary membership in Minnesota was 1,632, including twenty-members-at-large. In counties where auxiliaries are not organized, wives of physicians in good standing may become members-at-large. Wives of physicians who are members of their county societies and widows of physicians who are in good standing at the time of death, are eligible for membership.

HENNEPIN AUXILIARY CHANNELS FUND TO MENTAL HYGIENE WORK

Mrs. R. F. Erickson

In addition to its customary philanthropies, the Hennepin County Auxiliary has voted to donate $500 to the Minnesota Mental Hygiene Society. Financial needs of this organization at the present time, plus the interest of Governor Youngdahl and the public, influenced the Auxiliary in its decision.

After analyzing the work of this society, the members agreed that financial support was only the beginning; voluntary service is needed too, particularly in educating the public to the care and treatment of mental patients.

Dr. R. F. Erickson and Mrs. Elmer Rusten discussed proposed state and national medical legislation at the January luncheon and legislative day of the Hennepin County Auxiliary. Interest generated by the meeting has led to the planning of a series of round-table discussions on pending legislation.

NICOLLET-LE SUEUR GROUP TO AID HEART FUND DRIVE

At the November 29 business meeting, the Nicollet-Le Sueur Auxiliary agreed to aid the Minnesota Heart Association in its drive, slated for February 7 to February 28. The doctors' wives were to distribute plastic heart-shaped containers for collections throughout the two counties.

Progress on the year's program was recounted; the auxiliary is continuing its work in medical and surgical relief, cancer dressings, the sale of *Hygeia,* and the tuberculosis essay contest.

Mrs. Lawrence Sjostrom, St. Peter, has been chosen as a member of the State Cancer Board.

RENVILLE AUXILIARY JUDGES TUBERCULOSIS ESSAYS

Tuberculosis essays were judged at the December 14 meeting of the Renville Auxiliary, with the $5 prize going to a Bird Island girl.

The Auxiliary and Medical Society meetings were held concurrently, the Auxiliary members meeting at the Olivia Sweet Shop for dinner.

In Memoriam

HARRY FREDRICK BAYARD

Dr. H. F. Bayard of Minneapolis died on January 14, 1949, at the age of fifty-one.

Dr. Bayard was born in St. Paul March 14, 1897. He received his medical degree from the University of Minnesota Medical School in 1921 and interned at Minneapolis General Hospital.

After practicing at Stewartville, Minnesota, from 1923 to 1928, he took postgraduate work in proctology at the Mayo Foundation, Rochester, and began practicing his specialty in Minneapolis in 1931.

He was Assistant in Surgery on the Proctological Outpatient Service at the University of Minnesota and was a staff member at St. Barnabas Hospital.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations, the American College of Surgeons, the Alpha Kappa Kappa medical fraternity and Phi Sigma Kappa.

Dr. Bayard is survived by his wife, Florence L., his mother, Mrs. F. L. Bayard of Minneapolis, four sisters, and two brothers.

ALFRED HOFF

Dr. Alfred Hoff, well-known internist of Saint, Paul, died suddenly October 9, 1948, at his home, following an illness of several months.

Alfred Hoff was born March 9, 1883, in Saint Paul. He received his preliminary education in the schools of Saint Paul and was graduated from Cleveland High School in 1901. After working in the auditing department of the Northern Pacific Railroad for a time, he enrolled in the University of Minnesota, receiving his Bachelor of Science degree in 1908 and his Doctor of Medicine in 1910. He was a member of the Nu Sigma Nu fraternity and was elected to the Sigma Xi and Alpha Omega Alpha honorary fraternities.

Dr. Hoff served his internship at the City and County Hospital 1910-1911 and continued his connection with this hospital in various capacities, having been chief of the section in medicine and a member of the intern committee at the time of his death. In 1926, he took postgraduate work at the University of Vienna. On returning to Saint Paul, he confined his practice to internal medicine.

Dr. Hoff served as chief of staff of St. Luke's Hospital and was a member of the board of directors of this hospital. He was a Fellow of the American College of Physicians, certified by the American Board of Internal Medicine and also a member of Ramsey County Medical Society, the Minnesota State Medical Associa-

Theocalcin

tion and American Medical Association. He was a member of the Minnesota Society of Internal Medicine and of the Minnesota Academy of Medicine.

Dr. Hoff was married December 1, 1926 to Miss Marjorie Monkhouse. He is survived by his wife, son, John, and daughter, Mary Patricia; also two sisters and one brother.

Dr. Hoff was an ardent student in many phases of medicine. He devoted considerable time to the training of the intern staff and nurses of the Ancker and St. Luke's Hospitals. He was held in respect and esteem by his associates for his professional ability and integrity.

C. K. WILLIAMS, M.D.
E. V. GOLTZ, M.D.

J. ARTHUR JOHNSON

Dr. J. Arthur Johnson of Saint Paul passed away after a protracted illness at Mounds Park Hospital on November 10, 1948, at the age of fifty-four.

Arthur Johnson was born in Saint Paul on December 20, 1893. He attended Johnson High School in Saint Paul, but was forced to leave because of illness. He later received his high school diploma at Minnesota College in Minneapolis. He attended the University of Minnesota, where he received his B.S. degree. He completed his medical education in 1927 and was graduated with honors, and interned at Ancker Hospital in Saint Paul.

He was a member of Phi Chi medical fraternity and A. O. A. honorary medical fraternity. While obtaining his education, Dr. Johnson supported himself as a male nurse at Gillette and Mounds Park Hospitals. He was associated with the Earl Clinic of Saint Paul from his graduation until the time of his death. He was a member of the staffs of Midway and Mounds Park Hospitals. He was also a member of Ramsey County Medical Society, Minnesota State Medical Association, American Medical Association, and American Academy of General Practice.

On January, 1932, he suffered a stroke which left him with a partial left hemoplegia. At that time he was away from his practice for about a year. In spite of his disability he was able to carry on an active practice until the time of his death, although in more recent years his practice was limited almost entirely to allergy.

Dr. Johnson was especially interested in youth work and for many years was director of the young men's and boys' activities at the Gustavus Adolphus Lutheran Church of Saint Paul. Many a young physician owes his medical education to the encouragement and financial assistance given by him.

Dr. Johnson never married. He is survived by a sister, Mrs. Edith Rohr of Saint Paul, and two nieces, Mrs. Chas. Treanor and Carolyn Rohr.

J. L. NOBLE, M.D.

Of General Interest

Dr. H. L. Berge, formerly of Isle, has become associated in practice with Dr. W. F. Nordman in Mora.

A hospital for the care and treatment of Nervous and Mental disorders. Quiet, cheerful environment. Specially trained personnel. Recreational and occupational therapy.

Psychiatrists in Charge

L. R. Gowan, M.D. L. E. Schneider, M.D.

At the annual meeting of the Southern Minnesota Branch of the American Academy of General Practice, held in Mankato in December, Dr. D. H. Dewey of Owatonna was elected president of the group. Other officers elected were Dr. Otto B. Fesenmaier, New Ulm, vice president, and Dr. Roger G. Hassett, Mankato, secretary-treasurer.

* * *

Dr. Gordon R. Kamman of Saint Paul addressed the Stearns-Benton Medical Society in St. Cloud on Thursday, January 27. His subject was "Neuropsychiatric Conditions Commonly Seen in General Office Practice." Dr. Kamman recently addressed the Missouri Society of Neurology and Psychiatry in Kansas City on "The Value of the Rorschach Test."

* * *

Dr. Donald R. Lannin has opened an office at 455 Lowry Medical Arts Building, Saint Paul, for the practice of orthopedic surgery. Dr. Lannin graduated from the University of Minnesota Medical School in 1940, served in the Navy from 1941 to 1945, and has been a resident in orthopedics at the University and Shriners' Hospitals for the past three years.

* * *

Officials of the Minnesota Division, American Cancer Society, announced on December 25 that $5000 had been granted the University of Minnesota to finance a hormonal study in cancer research. The grant, made for the Dr. William A. O'Brien fellowship, will aid the cancer biology work of Dr. Robert A. Huseby, who is conducting a study on the response of breast cancer to hormone therapy.

* * *

Dr. Robert Bailey, Fairmont, announced in December that he planned to close his practice in the city in mid-January to accept a surgical residency at St. Monica's Hospital in Phoenix, Arizona. Dr. Bailey, a son of the late Dr. H. B. Bailey of Fairmont, opened his practice in Fairmont in December, 1945, after three and one-half years of military service.

* * *

Citizens of Jeffers, anxious to have a physician locate in the community, announced on December 28 that L. A. Duroe, of Jeffers, had given the village an eight-room residence to be used as a home and office for a physician if one could be found. At the time the gift was announced, civic organizations had been trying for a long time, unsuccessfully to obtain a doctor for the community. Residents hoped that the new inducement might solve their medical problem.

* * *

After nine years with the Worthington Clinic, Dr. W. R. Schmidt announced in December that on January 1 he would leave Worthington to become a resident in chest surgery at the Minneapolis Veterans Hospital. During World War II, Dr. Schmidt served with the armed forces in the South Pacific area. His position at the Worthington Clinic is being filled by Dr. William

Pratt, who recently completed a four-year fellowship in surgery at the Mayo Clinic.

* * *

It was announced on December 29 by Dr. G. M. A. Fortier, Little Falls, that Dr. Scott J. Mighell, formerly of Minneapolis, would join the staff of the Little Falls Medical Clinic on January 4. A graduate of the University of Iowa Medical School, Dr. Mighell served his internship at Philadelphia General Hospital and then entered the U. S. Air Forces, being stationed in Japan and the Philippine Islands. He has taken postgraduate work at the University of Minnesota Hospitals.

* * *

Dr. M. S. Rayman, formerly of Chicago, joined the staff of the Two Harbors Community Health Center and Clinic early in December. A graduate of the Columbia University Medical School, Dr. Rayman interned at Michael Reese Hospital, Chicago, and then took postgraduate training at Pennsylvania State Hospital and at the Newark Beth Israel Hospital, New Jersey. Before moving to Two Harbors, he was practicing in Darwin, California.

* * *

Gonvick again procured the services of a physician on January 1, when Dr. Norman F. Stone, formerly of Minneapolis, arrived in the community to open offices for the practice of medicine. His arrival filled the local medical gap that had existed since the death of Dr. John Stevens in 1947. Dr. Stone, a graduate of the University of Minnesota Medical School in 1944, has served in the Navy, practiced briefly in Mankato, and taken postgraduate work at the University of Minnesota Hospitals.

* * *

Dr. F. C. Anderson, after two and one-half years of practice in Little Falls, announced on December 18 that he would be associated with Dr. A. J. Olson in the practice of medicine at Owatonna after January 1. The two physicians, both former residents of Cloquet and friends since childhood, took their college training together. During his stay in Little Falls, Dr. Anderson was associated with Dr. R. V. Fait and Dr. D. L. Johnson.

* * *

In November, Dr. Osmund A. Wisness moved from Minneapolis to Slayton to become associated with the Doms-Pierson Clinic there. A graduate of the University of Minnesota Medical School in 1945, Dr. Wisness interned at the University of Maryland and then served for two years in the army. Following his discharge in February, 1948, he took residency training at Fairview Hospital, Minneapolis, where he remained until moving to Slayton in November.

* * *

Early in January, Dr. Sidney F. Becker, after two years of association with the Bemidji Clinic, announced his affiliation with Dr. E. W. Johnson, Bemidji, in the general practice of medicine and surgery. A graduate of the University of Minnesota Medical School in 1942, Dr. Becker served in the Navy for three and one-half years and then engaged in general practice at Thief

River Falls for a short time. Before moving to Bemidji in January, 1947, he took postgraduate training at the University of Minnesota for six months.

* * *

At the annual meeting of the Minnesota Association of Coroners in St. Cloud in December, Dr. E. A. Kilbride, Worthington, Nobles County coroner, was elected president of the group. He succeeds Dr. John W. Ekblad, Duluth, St. Louis County coroner, in the office.

Other officers elected at the meeting were Dr. R. H. Puumala, Cloquet, Carlton County coroner, first vice president, and Dr. J. N. Libert, St. Cloud, Stearns County coroner, second vice president. Dr. Russell Heim, Minneapolis, Hennepin County coroner, was re-elected as secretary-treasurer.

* * *

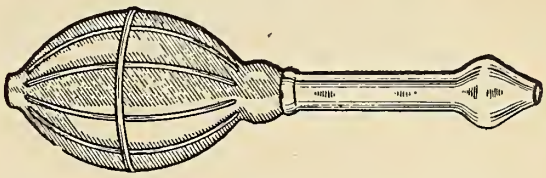
Plans to open a clinic in Minneapolis for pre-school children with cerebral palsy were announced on January 5 by the Minneapolis Junior League and the Minnesota Society for Crippled Children and Adults. Chairman of a medical committee connected with the development of the clinic is Dr. E. J. Huenekens, Minneapolis. At the clinic, which will open about May 1, children suffering from cerebral palsy will be "screened" in regard to capabilities for education by the University of Minnesota's Institute of Child Welfare. Children with the affliction must be referred to the clinic by physicians.

* * *

Four of the Minnesota physicians who attended a one-week course in child psychiatry at the University of Minnesota Center for Continuation Study, December 6 through 11, were Dr. John Stam, Worthington; Dr. Harold L. Stemsrud, Alexandria, and Dr. Russel E. Carlson and Dr. Henry Van Meier, both of Stillwater.

The course, which was given with the co-operation of the U. S. Public Health Service and the Minnesota Department of Health, was attended by fifty-two pediatricians and general practitioners from the United States and Canada.

* * *



It was announced on January 4 that Dr. James C. Masson, chief of the Mayo Clinic's surgical staff since 1935, had retired at the age of sixty-seven. Dr. Masson had been chief surgeon since the death of Dr. Edward Starr Judd, who had succeeded Dr. William J. Mayo in the post.

A graduate of the University of Toronto, Canada, Dr. Masson went to Rochester in 1912 as an intern at St. Mary's Hospital. In 1913 he became a first assistant in surgery, and in 1915 he was appointed head of a section in surgery. From 1946 until his retirement he served as a senior consultant on the clinic staff.

* * *

Dr. Howard Lundy Sather has been appointed a Lieutenant (jg), Medical Corps Reserve, U. S. Naval Reserve, according to an announcement by the Minneapolis Office of Naval Officer Procurement. He is now serving his internship at Ancker Hospital, Saint Paul, Minnesota. The son of Mr. and Mrs. Clarence Sather of Minneapolis, Dr. Sather attended the University of Marquette where he received his M.D. degree in June, 1948. He is a member of the medical fraternity, Alpha Kappa Kappa. He was sworn into the Navy at the Office of Naval Officer Procurement in Minneapolis.

"DEE"
NASAL SUCTION PUMP

Nasal Suction through its mechanical action aids

(1) In dislodgment or removal of mucoid or purulent secretion.

(2) In clearing the nasofrontal duct and sinus ostia establishing normal aeration.

(3) Through massage.

The "DEE" Nasal Suction Pump fulfills the following requirements.

Utility **Efficiency**
Cleansability **Simplicity**
Practicality

The Glass Tip fits child and adult—Price $2.50

The Nebraska State Legislature recently passed a resolution to the effect that whereas the American people enjoy the highest level of health, the best standards of scientific medical care and the finest medical institutions in the world, and whereas there has been a progressive deterioration of medical standards in countries where the government has assumed control of medical care, that the Nebraska State Legislature respectfully requests the Congress of the United States to refrain from imposing upon the citizens of this nation any form of compulsory health insurance or any system of medical care designed for national bureaucratic control.

Smith, Kline & French Laboratories of Philadelphia awarded in 1948 a total of seventy-three grants amounting to $314,761 in support of medical research, according to an announcement by Mr. W. Furness Thompson, Vice President in charge of research. Twenty-seven of these grants were made to twenty medical schools, and the balance to institutes, clinics and individual investigators. The funds were provided

under three main categories: as scholarships and fellowships; as aids to preclinical research in such fields as pharmacology, bacteriology, biochemistry, histology, microanalysis, mycology, organic chemistry, pharmaceutical chemistry and physical chemistry; and for support of investigations in various fields of clinical medicine as hypertension, pain, cardiovascular conditions, epilepsy, anemia, dermatology, obesity, et cetera.

Among Minnesota physicians who attended a three-day continuation course in cancer at the University of Minnesota, December 2 through 4, were Dr. F. W. Bachnik, Hibbing; Dr. R. G. Hankerson, Minnesota Lake; Dr. Nels N. Sonnesyn, Le Sueur; Dr. Francis M. McCarten, Stillwater; Dr. C. L. Roholt, Waverly; Dr. A. J. Lenarz, Browerville; Dr. Richard P. Griffin, Benson; Dr. Leroy J. Larson, Bagley; Dr. C. A. Boline, Battle Lake; Dr. Douglas L. Johnson, Little Falls; Dr. John A. McIntyre, Owatonna; Dr. Charles Vandersluis, Bemidji; Dr. H. A. Burns, Anoka; Dr. Carl Lundell, Granite Falls, and Dr. Walter S. Neff and Dr. Robert P. Pearsall, both of Virginia.

During the course, which was given for non-metropolitan physicians, the attending doctors had an opportunity to inspect the Cancer Detection Center at the University of Minnesota and to study the results of the hundred of examinations that have already been given there. Part of the course consisted of discussions of the techniques and newest developments in cancer diagnosis and treatment.

Red Cross Blood Centers.—The American Medical Association's Blood Bank Liaison Committee with the American Red Cross has been informed that nineteen blood bank programs, including the statewide service in Massachusetts, were in operation as of December 20, 1948. More than 97,000 pints of blood have been collected and made available without charge to physicians at 614 hospitals and forty-two clinics.

Since the opening of the first center in Rochester, New York, a year ago, centers have been established in Wichita, Kansas; Stockton, Los Angeles and San Jose, California; Atlanta; Washington, D. C.; Tucson; Omaha; Springfield and St. Louis, Missouri; Charlotte, North Carolina; Detroit and Lansing, Michigan; Yakima, Washington; Great Falls, Montana; Columbus, Ohio, and Saint Paul. Scheduled for early opening are regional centers at Portland, Philadelphia, Nashville, Boise and Louisville.

Dr. Carl Buturf, Freeborn physician, whose retirement to Minneapolis after thirty-seven years of rural practice was announced in the January issue of Minnesota Medicine, decided after one month of city life to "un-retire." Early in January, he and Mrs. Buturf moved from the Minneapolis home they had occupied since Thanksgiving, back to the community they had lived in for almost forty years. There, in Freeborn, Dr. Buturf reopened his office and his drug store, and began again the practice he had conducted for so many years. The community residents, to whom Dr. Buturf has been and still is their only physician, happily welcomed his return and promised to redecorate the medical office.

Now, Dr. Buturf, who says, "The city's all right, but —," plans to build a new home on the shores of Lake Freeborn, where Mrs. Buturf can grow wild flowers and where there is "plenty of space to move around in."

* * *

Forty years of medical service in Worthington were ended by Dr. B. O. Mork, Sr., when he retired on January 1 at the age of eighty-one.

Born in Norway, Dr. Mork came to the United States at the age of nineteen. After working for several years at the Indian agency in Granite Falls, he studied at Hamline University and was graduated in 1898. He then served for several years as a school teacher, before returning to Hamline to obtain his medical degree at the age of forty. In 1908 he moved to Worthington and formed a medical partnership with a Dr. Henry Wiedow. With four associates, Dr. Mork organized the Worthington Clinic in 1920.

Dr. Mork has two sons, both prominent Worthington residents. Dr. B. O. Mork, Jr., is director of Public Health District No. 5, and Raymond Mork is the Nobles County attorney.

* * *

Dr. D. A. Dukelow, director of the health and medical care division of the Hennepin County Community Chest

and Council since November, 1945, has been named medical consultant on health and fitness for the American Medical Association in Chicago. He will leave Minneapolis near the end of February to assume his new duties early in March.

A former practitioner in St. Charles, Dr. Dukelow was director of public health education for the Minnesota Department of Health from July, 1937, to November, 1945. He has been secretary of the public health education section of the American Public Health Association since October, 1947, and executive secretary of the Minnesota Public Health Conference since January, 1947.

In his new position with the AMA, Dr. Dukelow will be a consultant to school administrators and physicians associated with school health programs.

* * *

"Shall the Federal Government Provide Health Insurance?" That was the debate question at a Minneapolis Town Meeting held on January 10, with a Minneapolis physician, Dr. Max Seham, urging federal compulsory health insurance and declaring, "We can no longer be satisfied with half-way measures and patch-work proposals. By their very nature they [voluntary plans] cannot furnish the medical services that the majority of the people today need and want. They are too expensive." To provide adequate health protection for the groups who need it most, he said, "the only alternative is to enact such a program as proposed by Senator Murray and his associates in his last bill."

Taking the affirmative with Dr. Seham in the debate was Robert Gannon, state CIO legislative representative. Upholding the negative were Dr. M. M. Weaver, assistant dean of the University of Minnesota Medical School, and Carl A. Ernst, president of the Minnesota Association of Accident and Health Underwriters. Mr. Ernst asserted, "What seems to be overlooked by labor in this country is that when these social security programs cover the entire population, everyone will be up to his neck in the compulsion of taxes. Once completely under government control, labor will go the way of labor in other countries."

HOSPITAL NEWS

For the first time in the history of Asbury Hospital, Minneapolis, the medical staff is headed by a woman. Dr. Ann W. Arnold was elected president of the staff at its annual meeting in December. A graduate of the University of Pennsylvania Medical School, Dr. Arnold has practiced in Minneapolis since 1925.

Other staff officers elected at the meeting were Dr. Paul J. Preston, vice president, and Dr. Wayne S. Hagen, secretary-treasurer.

* * *

Dr. C. B. Nessa, St. Cloud, was elected chief of staff at the St. Cloud Hospital at a staff meeting on December 13. Other officers elected include Dr. N. F. Mussachio, Foley, vice president, and Dr. E. V. Wetzel, St. Cloud, secretary.

Cairns discussed the problems facing the city hospital because of the additional burden caused by the closing of the government hospital for Indians at Pipestone. He pointed out that hospitals throughout the county would have to assume the extra patient-load, and that facilities at the Redwood Falls Hospital were already being used to capacity. "We can only hope our present facilities can be expanded," he said. The hospital superintendent, Anna C. Rindal, said that the staff was eager to serve Indian patients needing medical care but that there simply was no room for more patients in the twenty-two-bed hospital.

* * *

Dr. Reuben A. Johnson was named president and chief of staff of Abbott Hospital, Minneapolis, at a meeting of the medical staff in December. Other officers elected include Dr. Ralph E. Creighten, vice president, and Dr. Elizabeth Lowry, secretary.

* * *

It was announced on December 9 that Dr. J. J. Smyth, Lester Prairie, and Dr. C. A. Anderson, Hector, had become members of the Glencoe Municipal Hospital staff.

* * *

As part of the program of Mental Health Week, Dr. E. W. Miller, superintendent of the Anoka State Hospital, addressed a group of state senators, representatives, heads of civic groups, clergymen and county and city officials at a meeting held at the hospital on December 2. Dr. Miller discussed the history of the Anoka hospital, false economies that had been attempted in the past, present problems in personnel, new techniques for handling patients, and hospital requirements for the future. He listed the reasons for the hospital's request for a larger legislative appropriation, and asked his listeners to do what they could to promote the success of the program.

The West Side General Hospital, Saint Paul, which was founded nearly forty years ago by the late Rev. John M. Bartmeier, has been reorganized through the efforts of the Riverview Commercial Club and will be operated by a new corporation as the Riverview Memorial Hospital. The directors are West Side citizens, with Herman C. Marthaler, president; Leroy Weir, vice president; Walter Perlt, secretary, and Julius H. Brogmus, treasurer. Mr. Conrad Swanson, manager of the Riverview Commercial Club, is the acting manager of the hospital. The present medical staff, of which Dr. Herman Kesting is chief, and the present superintendent, Miss Genevieve Courteau, will continue.

Charles M. McLean, a recent graduate of the Washington University School of Hospital Administration, has assumed the duties of assistant superintendent at Ancker Hospital, Saint Paul, under the direction of Dr. Thomas Brodie.

BLUE SHIELD NEWS

Applications covering Blue Shield participant subscribers received as of December 31, 1948	130,639
Blue Shield cases paid from December 1 to December 31, 1948	972
Total, 1948	4,431
Amount paid on Blue Shield cases from December 1 to December 31, 1948	$ 37,415.45
Total, 1948	166,229.63

At the close of 1948 the goal of securing 100,000 persons in Minnesota desiring the Blue Shield contract was achieved. In fact, this total was exceeded by 30,639. This is quite a distinction for Minnesota Medical Service Inc., for no other plan has ever reached such a figure in its first year of operation; of the total applications, representing 130,639 participant subscribers, contracts

ROUGH HANDS FROM TOO MUCH SCRUBBING?

Soften dry skin with AR-EX CHAP CREAM! Contains carbonyl diomide, shown in hospitol test to moke skin softer, smoother, ond even whiter! *Archives of Derm. ond S., July, 1943*

AR-EX CHAP CREAM

AR-EX COSMETICS, INC., 1036 W. VAN BUREN ST., CHICAGO 7, ILL.

covering approximately 102,000 subscribers were in effect as of December 31, 1948.

Much credit is due the Enrollment Department of the Blue Cross-Blue Shield office for this wonderful record. Selling the Minnesota Blue Shield contract a year ago was not an easy task. The idea of a voluntary non-profit medical care plan was relatively new to Minnesota; therefore, a great deal of sales promotion was required. The subscription to this new contract meant an additional deduction from a pay check already subject to numerous deductions. The advantages of the Blue Shield contract had to be fully explained. Since the plan was so little known no "word-of-mouth" advertising was available, rather the bulk of the responsibility for selling the plan fell to the Blue Cross-Blue Shield representatives. It is gratifying to see that with much perserverance the enrollment in Minnesota Blue Shield has grown from 10,000 persons covered in February, 1948, to the current figure.

The co-operation of the doctors throughout the state in helping the representatives contact various organizations with a view toward introducing Blue Shield to farm bureaus and community groups has been of considerable assistance, for the doctors' support of Blue Shield is a definite factor in its favor. Now that the plan is well under way, the benefits derived have become obvious. The increasing number of letters of appreciation reaching the Blue Shield office daily bear out this statement.

The Blue Shield contract is at present sold only to groups of employed people and their dependents. Blue Shield expects to have available as soon as possible an individual contract for those who are not now eligible to receive a contract due to their employment status.

Blue Shield has shown a most favorable financial operating statement since its beginning. The co-operation of the doctors has shown no abuse of the plan. This is appreciated and undoubtedly will continue.

The Blue Shield Board of Directors is giving consideration to the return of the funds sent by doctors to finance the working capital of the plan. The plan for returning these funds must also meet the approval of government authorities as to when they may be returned without impairing the guarantee of the service to subscribers.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

CONTROL OF PAIN IN CHILDBIRTH. Third Edition. Clifford B. Lull, M.D., F.A.C.S., F.I.C.S. Director, Division of Obstetrics and Gynecology, Philadelphia Lying-In Unit Pennsylvania Hospital, and Robert A. Hingson, M.D., F.I.C.S., F.A.C.A., F.I.C.A. Associate Prefessor of Obstetrics; anesthesiologist Department of Obstetrics, Johns Hopkins University and Hospital; surgeon, United States Public Health Service. 522 pages. Illus. Price, $12.00, cloth. Philadelphia: J. B. Lippincott Co., 1948.

TWENTIETH CENTURY SPEECH AND VOICE CORRECTION. Edited by Emil Froeschels, M.D. President, International Society for Logopedics and Phoniatrics; president New York Society for Speech and Voice Therapy. 321 pages. Price $6.00, cloth. New York: The Philosophical Society, 1948.

SYNOPSIS OF PEDIATRICS. John Zahorsky, A.B., M.D., F.A.C.P., Professor of Pediatrics and Director of the Department of Pediatrics, St. Louis University School of Medicine, and Pediatrician-in-Chief to the St. Mary's Group of Hospitals; Fellow of the American Academy of Pediatrics. Assisted by T. S. Zahorsky, B.S., M.D., Senior Instructor in Pediatrics, St. Louis University School of Medicine, and Assistant Pediatrician to the St. Mary's Group of Hospitals. 5th ed. 449 pages. Illus. Price $5.50. St. Louis: C. V. Mosby Co., 1948.

The fifth edition of this well-known synopsis maintains its excellent presentation of clinical pediatrics in capsule form. The material is well presented in a readable and highly condensed form.

There are a few omissions. For example, no mention is made of primary atypical pneumonia, nor are antihistaminics mentioned in the treatment of hay fever, urticaria, or serum disease.

However, the book has been brought up to date throughout and is an excellent and authoritative treatise on the essentials of pediatrics.

B. C. Adler, M.D.

PRACTICE OF ALLERGY. By Warren T. Vaughan; revised by J. Harvey Black. 2nd ed. 1092 pages. Illus. St. Louis: C. V. Mosby Company, 1948. Price $15.

Warren Vaughan's second edition of this classic text has been greatly delayed by his untimely death in 1944. Much of the present material is his own revision, but the whole contents had to be reviewed by the second author before the latter's editorship could begin. The subject matter retains the charm and flavor of Vaughan's original edition which makes it by far the most enjoyable reading of any of the treatises on allergy. The volume is printed on good quality stock and contains 1131 pages with many illustrations, most of them by the author himself, one of whose hobbies was photography.

Several outstanding features are presented. A thirty-page bibliography includes over 1,000 articles and represents essentially all of the important ones in the allergic field. The sections on food allergy and on pollens and pollinosis are exhaustive and the most authoritative obtainable. Photographs in the latter section actually allow the reader to recognize the various hay-fever-producing grasses and weeds. Descriptions of the various families of foods, their origin, their use in manufacture and processing and their importance in producing sensitization are excellently handled. As presented, they are interest to both the student of the subject and to the more casual reader.

Despite the reviewer's thorough enjoyment of this book, certain omissions must be commented upon. Many readers would have enjoyed the inclusion of a discussion of the relation between allergic symptoms and the autonomic nervous system. This is a relationship which is apparent to all clinical practitioners of medicine, regarding which there is as yet little published work. There is a discussion of the inaccuracy of skin tests, but this is not carried to the point where the reader understands that the tests are only clues and that one cannot make the diagnosis of the allergic state by the application of these tests. There is little discussion of sensitization to oils and fats, probably because of the dearth of literature on this subject and information regarding it.

This volume can be unhesitatingly recommended to all medical readers. The authors' manner of expression is much more lucid than is common in American medical writing. Those reading for enjoyment may find it here, those seeking specific information will surely find their needs satisfied.

Florence Nightingale Saw the Light

She gave us the light to see the need for a major service in each community. If today you were to take our nursing service from us it would cause a great catastrophe. Nursing is a new profession.

Florence Nightingale started the first nurses' training school less than 100 years ago. Thanks to her for light, vision and inspiration.

Glenwood Hills also saw a light of similar quality 10 years ago when it felt this urgent need for properly trained *psychiatric nurses* to "serve the community, aid the doctor and care for the patient."

Competent, qualified trained nurses are taught by *"competent, qualified* and *trained instructors."*

You doctors can greatly help recruit students by selecting them in your community. Our best graduates come doctor-recommended.

Tuition is free. There is a small charge for matriculation. Help eliminate the nursing shortage by choosing a promising girl, 17 or over, in your community, and sending us her name.

OXYCEL®

hemostasis

In general surgery and in the specialized branches of surgery OXYCEL (oxidized cellulose, Parke, Davis & Company) aids the operator by stopping bleeding not readily controllable by clamp or ligature. This refinement in surgical technic is made possible by the the distinctive features of OXYCEL.

PACKAGE INFORMATION

OXYCEL is supplied in individual screw-capped bottles.

OXYCEL PADS (Gauze Type) Sterile 3″ x 3″ eight-ply pads.

OXYCEL STRIPS (Gauze Type) Sterile 18″ x 2″ four-ply strips, pleated in accordion fashion.

OXYCEL PLEDGETS (Cotton Type) Sterile 2¼″ x 1″ x 1″ portions.

OXYCEL FOLEY CONES Sterile four-ply gauze-type discs of 5″ or 7″ diameter folded in radially fluted form, used in prostatectomy.

The Balance Sheet

We are all striving mightily to set aside some portion of our income in reserve. This is not an easy task in this day of heavy taxation. Yet these reserves are important; to be used for contingencies that we cannot predict today. It's silly to be forced to stand idly aside and watch those reserves being dissipated through protracted periods of disability when you could have prevented it by the purchase of an outstanding Disability Policy.

It's only logic that indicates that your best plan of income protection is through the plan available to you through your Association.

Tomorrow may be too late—ACT NOW.

In Chronic Cholecystitis...

First & Foremost chemically pure bile acid derivative made available for therapy, Council-Accepted since 1932, exhaustively studied and most favorably reported by hundreds of investigators, Decholin® remains today a bile acid preparation for use in the medical management of chronic cholecystitis.

The Most Potent Hydrocholeretic,

Decholin multiplies and frees the flow of thinned liver bile. By thus easing biliary evacuation and closely simulating a physiologic drainage of accumulated foreign matter through the hepatic and common ducts, Decholin may lessen the epigastric and right upper quadrant discomfort typical of chronic cholecystitis, improve the patient's tolerance for food and reduce the periods of disability.

Decholin

dehydrocholic acid

3¾ gr. tablets in bottles of 25, 100, 500, and 1000.

Decholin Sodium® (sodium dehydrocholate) in 20% aqueous solution; ampuls of 3 cc., 5 cc. and 10 cc., packages of 3 and 20 ampuls.

The Fifth Edition of "Decholin in Biliary Tract Disturbances" is now available upon request.

Nutritional adjuvants and supplements

The extension of the usefulness of vitamins, beyond the specific deficiencies which they cure and prevent, is a therapeutic phenomenon of the past decade. Those who specialize in nutritional disease have frequently emphasized to physicians the doctrine that every cell in the body needs every vitamin all of the time. Today, fortunately, physicians are increasingly realizing the importance of the nutritional phase of medicine. Lederle has been pre-eminent in the vitamin field for many years. Its list of vitamin products includes combinations and single vitamins adequate for every clinical need.

MEAT...

In the Rational Weight Reduction Program

One dictum is universally recognized in the planning of reducing diets: the basic requirements of good nutrition remain unaltered, and adequate amounts of high-quality protein are the cardinal factor in the successful dietary management of overweight.

Protein allowance in such a program is stated to be not less than 1.5 to 1.7 Gm. per Kg. of ideal body weight.[1] A further advantage of the diet high in protein and low in fat and carbohydrate is its greater simplicity; the tedious calculation of calories may be omitted without impairing the efficacy of the program.[2]

It is therefore recommended that lean meat be given a dominant role in reducing diets.[1]

The protein content of meat is notably high. Regardless of cut or kind, meat provides biologically complete protein able to satisfy the multiple amino acid needs of the body.

Lean meat, particularly, is of excellent digestibility. Its outstanding satiety value assures patient cooperation, a vital factor in the success of any weight reducing program.

by far the most potent ORAL ESTROGEN available clinically

In exceedingly minute doses—as little as 0.02 mg. (1/3200 gr.) daily—ESTINYL* maintains the average menopausal patient free of symptoms. Even when initiating therapy and in the more severe cases, unusually small dosage—measured in hundredths of a milligram—has been found effective.

ESTINYL

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY

(ETHINYL ESTRADIOL)

ESTINYL, a derivative of the ovarian follicular hormone, estradiol, evokes the sense of well-being characteristic of natural hormone therapy. It acts rapidly, often completely controlling climacteric symptoms within a few days. In therapeutic dosage side effects are notably infrequent. Unique response to minimal dosage permits effective estrogen therapy at low cost to patients.

DOSAGE: One ESTINYL Tablet (0.02 mg.) or one teaspoonful of ESTINYL LIQUID (0.03 mg.) daily, may be prescribed, reducing dosage as symptoms subside.

ESTINYL Tablets, 0.02 (buff) or 0.05 mg. (pink), in bottles of 100, 250 and 1000.

ESTINYL LIQUID, 0.03 mg. per 4 cc. (teaspoonful), in bottles of 4 and 16 oz.

WHEN

SHE'S TEMPTED BY

FORBIDDEN FOODS...

What's a woman to do? She's tired of dieting. The vision of new health and a better figure faded with the first 10 pounds . . . and now all she can see wherever she goes is food, food, tempting food. • To depress her appetite, one 2.5-mg. tablet an hour before breakfast and lunch is usually sufficient, with perhaps a third tablet in midafternoon if it does not cause insomnia. The stimulating action of DESOXYN also elevates the mood and increases the desire for activity. • Investigators who have used DESOXYN extensively claim that it has these advantages over other sympathomimetic amines in producing euphoria and stimulation of the central nervous system: smaller dosage, quicker action, longer effect, relatively few side-effects.[1,2]

• In addition to its usefulness in obesity, DESOXYN has a wide variety of other uses—orally in the treatment of narcolepsy and for temporary use as a mental stimulant, parenterally to maintain blood pressure during surgery under spinal or regional block anesthesia. • DESOXYN Hydrochloride is safe and effective with the correct dosage. Why not give it a trial? For new literature on indications, contraindications and dosage, write to ABBOTT LABORATORIES, North Chicago, Illinois.

How mild can a cigarette be?

In a recent coast-to-coast test, hundreds of men and women smoked Camels—and only Camels—for 30 consecutive days. These people smoked on the average of one to two packages of Camels a day during the entire test period. Each week, throat specialists examined these Camel smokers. A total of 2,470 careful examinations were made by these doctors. After studying the results of the weekly examinations, these throat specialists reported:

"NOT ONE SINGLE CASE OF THROAT IRRITATION DUE TO SMOKING CAMELS!"

Money-Back Guarantee!

Test Camel mildness for yourself in your own "T-Zone." T for taste, T for throat. If, at any time, you are not convinced that Camels are the mildest cigarette you've ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. *(Signed)* R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina.

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel!

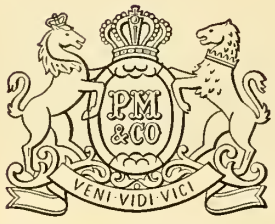
"CHANGE TO PHILIP MORRIS



OR...

CUT DOWN YOUR SMOKING!"

That is the suggestion of many of the country's leading specialists in cases of throat irritation.*

Many doctors have among their patients some who they believe smoke too much. But the difficulty of persuading such smokers to cut down is familiar to everyone. What better advice therefore than *"Change to Philip Morris"*...the only leading cigarette proved definitely and measurably less irritating.

To minimize cigarette irritants, Philip Morris are made by a special process whose advantages are conclusively shown in published studies.** These studies may convince *you too* that the most effective advice for patients who smoke is *"Change to Philip Morris."*

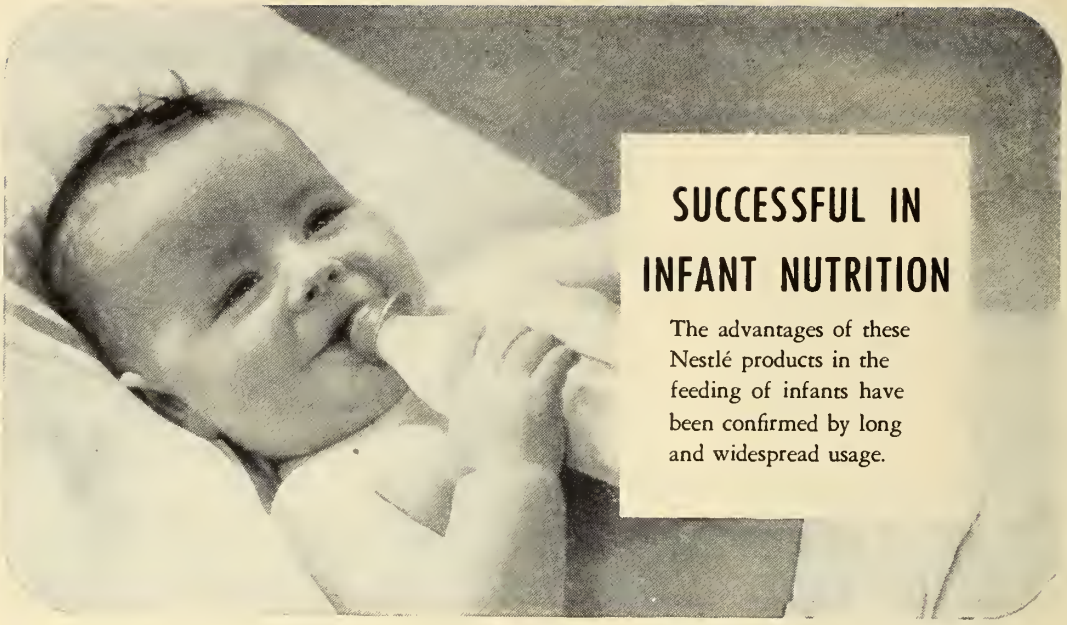
CAMP ANATOMICAL SUPPORT FOR FAULTY BODY MECHANICS

PATIENT OF THIN TYPE OF BUILD—
SKELETON INDRAWN

In conditions of faulty body mechanics, the nonuse of the abdominal muscles allows the pelvis to rotate downward and forward, bringing the sacrum up and back. There results an increased forward lumbar curve with the articular facets of the lumbar spine crowded together in the back.

The dorsal spine curves backward with compression of the dorsal intervertebral discs and the cervical spine curves forward with the articular facets in this region closer together. Therefore, chronic strain of the muscles, ligaments and joints of the spine and pelvis occurs.



Camp Anatomical Supports have an adjustment by means of which their lower sections can be evenly and accurately brought about the major portion of the bony pelvis. When the pelvis is thus steadied, the patient can contract the abdominal muscles with ease and then with slight movement straighten the upper back.

Relieving back strain and fatigue due to faulty body mechanics is a feature of the Camp Support illustrated and other types for Prenatal, Postnatal, Postoperative, Pendulous Abdomen, Visceroptosis, Nephroptosis, Hernia and Orthopedic conditions.

DIAGNOSIS AND TREATMENT OF NEUROSYPHILIS

HENRY W. WOLTMAN, M.D., and ROBERT R. KIERLAND, M.D.
Rochester, Minnesota

IN presenting the subject of syphilis of the nervous system, one may begin with the initial infection, trace its progression into the nervous system and describe the havoc it works there; or one may follow the course by which our knowledge of it was attained. The former is easier to do; the latter, we believe, is more instructive to the practitioner, and so we shall attempt this somewhat unorthodox approach.

We may start early, but not quite at the beginning, by noting that the versatile Girolamo Fracastoro, of Padua, was not only an astronomer like his colleague, Nicholaus Koppernigk, but also a poet and above all an eminent epidemiologist. Padua had been hit hard by a great pandemic, which this writer of hexameters traced to a shepherd called "Syphilus." "Lues" is a much older latin word that meant simply "plague," and only later was the term restricted to this particular plague.

It was the cutaneous manifestations of the disease that engrossed the early writers. They did speak of headache, but centuries passed before there appeared any enlightenment on the neurologic sequelae that assume so prominent a position in syphilitic symptomatology, and their history has been pieced together with uncertainty and in retrospect.

Dementia Paralytica

In his "Observations on Madness and Melancholia," in 1798, John Haslam offered a clinical portrayal of dementia paralytica, and in 1826, Calmeil coined the term "general paralysis of the insane." In a sense this term was poorly chosen. These patients do become demented but not paralyzed, although they often complain of weakness, take to bed early and simply stay there. In 1853, long before the discovery of the spirochete and positive reactions in blood and spinal fluid, Esquirol, the immediate successor of Pinel, suspected its syphilitic origin. In 1906, Wassermann's discovery implemented the statistical approach and in 1913, Noguchi and others were able to demonstrate the Treponema pallidum in the brain.

Dementia paralytica overtakes about 5 per cent of neurosyphilitics and usually becomes evident in patients between the ages of thirty and fifty years, some five to fifteen years after the initial infection. It appears earlier in men than in women and affects them at least twice as often. The onset is insidious and is characterized by slight defect in memory, conduct and personal appearance and by increasing irritability and fits of temper. There is a blunting for regard of social and moral conventions; the first overt impropriety may be the pouring of champagne into a lady's pocket or urinating on the street. The mood may become gay and generosity extravagant, or the patient may become depressed and hypochondriacal, or he may sink gradually into an apathetic dementia. He may become paranoid, delirious or merely somnolent. While these personality changes are in progress, there may be interspersed convulsions and strokes of various kinds. The final scene is one of intellectual dilapidation, im-

From the section on neurology and psychiatry (Woltman) and the section on dermatology and syphilology (Kierland), Mayo Clinic, Rochester, Minnesota.

mobility and filth. The course of the illness may be acute or chronic, but if untreated, it generally lasts about three years.

From a neurologic standpoint, the sagging, tremulous features and the slovenly articulation at once attract attention. The pupils may be irregular, small or unequal, and often show the Argyll Robertson phenomena. The tendon reflexes are usually increased. There may be palsies of the cranial nerves and signs of focal damage to the brain.

The blood and spinal fluid findings are more persistently positive than in any other type of neurosyphilis. The serologic tests of blood and spinal fluid for syphilis usually give positive results. In the spinal fluid small and large lymphocytes and occasional neutrophils are present, protein is increased and Lange's colloidal gold curve is usually zone one. The diagnosis of dementia paralytica should be based on clinical signs, but the blood and spinal fluid picture just described, even without conclusive clinical evidence, justifies anticipation of eventual general paresis and is often referred to as paresis sine paresi. Its clinical counterpart, but without syphilis, is referred to as pseudoparesis and may be caused by alcoholism, arteriosclerosis, lead poisoning and other toxic states.

Tabes Dorsalis

Wasting of the back, or tabes dorsalis, according to Gowers, was a designation already applied by Hippocrates to all chronic paraplegias. It was Romberg who restricted the term to a wasting of the posterior columns of the spinal cord. Priority for a description, in 1851, of tabes that leaves little to be desired and that relates the clinical picture to shrinking of the posterior roots and columns of the spinal cord is usually assigned to him. An equally familiar name of the syndrome we are discussing is "locomotor ataxia." To escape the usage of Greek words, "offensive alike to the tongue and to the ear," as Duschenne said in 1872, "I was obliged to call the disease after one of its chief symptoms, viz., the progressive loss of the co-ordination of movement. The name 'progressive locomotor ataxy' seems to me to give the most exact idea of this kind of motor trouble." Of syphilis, he said, "I could not feel certain as to the relationship of syphilis and locomotor ataxy." He was more inclined to think of "moral causes," by which he meant mental suffering, or to use the phrase so current nowadays, "psychosomatic." Fournier, in 1876, was the first to assert the wide extent of the relation of syphilis to tabes. As late as 1888, Gowers wrote "Among the individual causes, one overshadows all the rest—the influence of syphilis. The lesion is not syphilitic in histologic character. It is moreover rarely influenced by antisyphilitic treatment. It must be regarded as a degenerative sequel of syphilis rather than a true syphilitic disease." For much the same reason and because gummas were never found, the great Virchow, who had asserted that tabes was caused by syphilis, reversed his opinion.

The assembling of the hierarchy of tabetic symptoms and signs, relating them to disease of the posterior columns of the spinal cord and proving this condition to be due to syphilis can be said to have required the combined efforts of many workers. Here, as in paresis, the introduction of the Wassermann reaction and discovery of the Spirochaeta pallida in the spinal cord cleared away remaining doubt.

Tabes develops in less than 10 per cent of neurosyphilitics; it affects men more often than women, and symptoms and signs usually delay their appearance until five to fifteen years after the initial infection. One of the earliest symptoms is "lightning pains." Although not quite pathognomonic of tabes, it is so suggestive that its behavior merits more detailed consideration. Lightning pains may appear anywhere in the body, but they are much more common in the lower extremities and are more distinctive when they occur at some distance from a joint. They tend to come in showers, often in a dollar-sized spot, which in turn becomes sensitive to the lightest touch but not to heavy pressure. They may make the patient feel as though the area had been touched by a lighted cigaret, but they do not exceed seconds in duration. They may seem to be linear streaks of pain that explode terminally like a rocket. One physician who had tabes compared them to the flight of lightning bugs. Lightning pains may occur in diabetic neuritis, in multiple sclerosis, in syringomyelia, in migraine and sometimes without demonstrable cause.

Also common in tabes is the girdle pain which causes the patient to feel as though a belt had been drawn too tightly round the waist or thorax.

For still another type of pain, let us turn to one of Charcot's lectures: "But of all the visceral symptoms which may display themselves, from

the period of lightning pains, which is at once the most remarkable and the least known, if I mistake not, is that which I have proposed to designate by the name of gastric crisis. . . . But the connection which really exists between gastric crises and locomotor ataxy appears to me to have been pointed out for the first time, by M. Delamarre, author of a thesis bearing the date 1866 and entitled 'Gastric Troubles in Locomotor Ataxia.' "

Especially suggestive of gastric crises is a midline epigastric or abdominal pain that may be mild or gruesome in intensity, that begins abruptly, may continue for hours, days or weeks, and, if there is no additional complication such as gastric or duodenal ulcer, ends abruptly. A period of convalescence is missing, and the patient is found sitting up prepared to eat a banquet meal. During the crisis, the patient does not tolerate the lightest touch of a sheet on the abdomen but raises no objection to a fist sunk deeply into it. A gastric crisis may be attended or entirely replaced by nausea. The patient then presents a most pathetic sight as he lies over the edge of the bed with a stream of saliva running out of his mouth from morning until night.

For years either lightning pains or crises may constitute the whole symptomatology of the disease. Typical crises may also occur with migraine, or as a familial disorder, or they may remain unexplained. Other kinds of crises, too, such as laryngeal, testicular and rectal, may occur with neurosyphilis.

Blindness, caused by simple optic atrophy, may appear early or late, and ophthalmoplegias of the external ocular muscles are not infrequent.

A common symptom, indeed the one by which Duchenne called the disease, is locomotor ataxia. Moritz Heinrich Romberg, professor of medicine, University of Berlin, described it well:

"The rider no longer feels the resistance of the stirrup, and has the strap put up a hole or two. The gait begins to be insecure, and the patient attempts to improve it by making a greater effort of the will; as he does not feel the tread to be firm, he puts down his heels with greater force. From the commencement of the disease the individual keeps his eyes on his feet to prevent his movements from becoming still more unsteady. If he is ordered to close his eyes while in the erect posture, he at once commences to totter and swing from side to side; the insecurity of his gait also exhibits itself more in the dark. It is now ten years since I pointed out this pathognomonic sign . . . and it is a symptom which I have not observed in other paralyses, nor in uncomplicated amaurosis. . . ."

The explanation of this symptom caused great difficulty, since the posterior columns could be destroyed and yet the patient acknowledged no deficit in the appreciation of scratching, pricking or pinching the skin, since the relationship of the posterior roots to the posterior columns was not known and since the posterior columns of the cord seemed to be related to the cerebellum. It was generally thought that degeneration of the posterior columns intercepted cerebellar control.

Now let us hear what Charcot had to say, in 1868, about another phenomenon most often found in tabes:

"Allow me to fix your attention for an instant upon this species of articular affection, in which I take a paternal interest, all the more lively because the significance I attach to it has had to counter many skeptics. And at first, a word as to the clinical characters of the arthropathies of ataxic patients. . . . Without any appreciable external cause, we may see, between one day and the next, the development of a general and often enormous tumefaction of the member, most commonly without any pain whatever, or any febrile reaction. . . . On puncture being made, a transparent lemon-colored liquid has been frequently drawn from the joint. . . .

"One or two weeks after the invasion, sometimes much sooner, the existence of more or less marked cracking sounds may be noted, betraying the alteration of the articular surfaces. . . .

"Ataxic arthropathy usually occupies the knees, shoulders, and elbows; it may also take up its seat in the hip joints—it is in the grey matter of the anterior cornua of the cord that the starting point of this curious complication of the ataxia is to be found according to our belief."

Sensory impairment and trauma are conditions attending the development of Charcot's joints, but there is doubt that these insults alone suffice to explain the arthropathies. The same phenomenon may be expected to occur and does occur in syringomyelia.

Trophic ulcers, usually situated on the ball of the foot and so often associated with other diseases in which sensation may be impaired, such as diabetic neuritis and myelodysplasia, are of frequent occurrence in tabes.

It must be noted that tabes is by no means an unadulterated parenchymatous myelopathy. Meninges and vessels may be affected in characteristic syphilitic fashion and thus superimpose an endless variety of symptoms.

There are certain objective findings of tabes

that pre-empt our attention. First is the Argyll Robertson pupil which, properly considered, has five characteristics: the presence of vision, a small pupil, a pupil that contracts poorly or not at all to light, one that reacts to accommodation, and one that responds imperfectly to belladonna. In 1869, Robertson, whose full name is Douglas Moray Cooper Lamb Argyll Robertson and should not be hyphenated, published a paper bearing the title "On an Interesting Series of Eye Symptoms in a Case of Spinal Disease with Remarks on the Action of Belladonna on the Iris, and so forth" and somewhat later a paper entitled "Four Cases of Spinal Myosis with Remarks on the Action of Light on the Pupils." Romberg had previously mentioned a contraction, even to the size of a pinhead, with loss of motion in one or both eyes. Merritt and Moore pointed out that there is only one situation in which a lesion can destroy both the light reflex and the sympathetic pathway and this is just ventral to the posterior commissure. The incomplete Argyll Robertson pupil has been seen unrelated to syphilis in epidemic encephalitis, alcoholism, tumor, syringomyelia and rarely as an heredofamilial characteristic. A small pupil that contracts to a point on conversion may also be observed with postural hypotension but not necessarily because of it. A larger pupil that reacts so very slowly to light and to conversion that this may escape notice and so be mistaken for the Argyll Robertson sign is the tonic pupil. Unfamiliarity with it may cause even greater confusion when it is coupled with loss of one or more tendon reflexes. This is a harmless situation known as Adie's syndrome.

Next, perhaps, should be mentioned loss of the tendon reflexes. Karl Westphal, in 1875, was the first to point out that a lost knee jerk is one of the earliest and most constant signs of tabes. Such loss is readily explained by encroachment of the pathologic process on the posterior roots, thereby interrupting the reflex arc.

Disease of the posterior roots probably accounts also for the involved pattern of sensory disturbance, one of the cardinal findings by which we may recognize tabes dorsalis as such. Appreciation of touch, pain and temperature may be impaired, lost or perverted, individually or in various combinations. The distribution of these changes is segmental, and the parts affected most commonly are the lower extremities, then the thorax and median aspects of the upper extremities, and finally the face. A pin applied to a toe or the dorsum of the foot may bring forth prompt acknowledgment of contact, but only seconds later an appreciation of pain, not a bright pain but a lingering and sometimes repetitive burning sensation that may be referred to some entirely different location, such as the opposite extremity. So kaleidoscopic a series of sensations may be provoked by a few pin pricks that the examination may have to be interrupted until they subside. Similar hyperpathic and perverted sensations also occur in syringomyelia, multiple sclerosis and neuritis. It is important that the thoracic zone be examined with care since sensory changes here are particularly helpful in diagnosis but are often overlooked. The sensory loss may be profound. Oppenheim spoke of a woman who had unknowingly pinned a corsage directly to her breast and had worn it throughout an evening's entertainment.

A patient having tabes is often exquisitely sensitive to changes in temperature, so that the application of a cold test object to the abdomen or of a tincture to the back before making a spinal puncture may all but send him flying to the floor.

Appreciation of movements of the joints, especially of the toes, may be difficult. In tabes this loss is often greater than is loss of appreciation of vibration and in this respect differs from the usual finding in subacute combined degeneration of the spinal cord.

Sensitivity of deeply lying structures is often impaired more profoundly than is sensitivity of the overlying skin. This disassociation is one of the most characteristic features of tabes and almost at once distinguishes it from polyneuritis, in which superficial sensation may also be impaired. Since muscles, larger nerves, eyeballs, epigastrium and testicles may be viciously squeezed without eliciting discomfort, care should be exercised in carrying out tests related to these structures. A gastric ulcer may perforate or an appendix may rupture without giving the attending physician any warning that a catastrophe is under way.

The sphincters are often relaxed and the finding of a cord bladder is common and diagnostically helpful.

The signs we have described usually serve to distinguish tabes from other neurologic disorders, such as cerebellar disease and polyneuritis. Combined sclerosis of the spinal cord may be simulated, and it is not surprising that, in 1884, Lichtenstern

wrote on tabes complicated by progressive pernicious anemia. Two years later, Lichtheim reversed the sequence and reported pernicious anemia complicated by subacute combined sclerosis. Occasionally a trap is set. When these patients were treated with arsenicals, they sometimes became even more disabled, and in consequence antisyphilitic treatment was intensified. Thus a superimposed arsenical polyneuritis reached really serious proportions. The greatest difficulty in diagnosis, however, arises in cases that really justify use of the term "pseudotabes diabetica." The resemblance to tabes may be very close; however, the diabetes, the absence of serologic evidence of syphilis and the finding of normally tender muscles, incongruous to the picture of true tabes dorsalis, lead to the decision that the condition is diabetic neuropathy. It must be admitted that there may be cases of true tabes with glycosuria and negative evidence on serologic examination.

Dementia paralytica and tabes are sometimes concurrent, the condition then being described as taboparesis.

Tabes and paresis, usually in conjunction, may follow congenitally acquired syphilis but differ relatively little from their expression in adults. The juvenile variant usually begins between the ages of nine and sixteen years. As would be expected, the juvenile taboparetic usually presents a simpler deteriorating deficiency, and the stigmas of congenital syphilis, such as keratitis and Hutchinson's teeth, create a classic picture.

Examination of the spinal fluid in tabes usually shows some increase in the lymphocytes; the serologic reactions for syphilis in blood and cerebrospinal fluid are usually positive and the gold sol reaction abnormal, usually with precipitation in the second zone.

Vascular Neurosyphilis

Large and small blood vessels, and particularly the arteries of the brain, may undergo perivascular cuffing, intimal changes and closures with results dependent on the part of the brain damaged by the affected vessel. The onset is usually stroke-like and there may be hemiplegia, aphasia, hemianopsia, bulbar symptoms, stupor and convulsions. The spinal cord, too, may become infarcted, with resulting paraplegia and incontinence, Brown-Séquard syndrome, syndrome of the anterior spinal artery, spastic paraplegia and an asymmetric variety of poliomyelitis. Closure of the veins likewise may occur and lead to myelomalacia. Associated with these vascular insults there is usually meningeal involvement as well.

There is no neurologic ensemble caused by disease of blood vessels that is pathognomonic of syphilis. A syphilitic etiology must be established from the content of the history and from other clinical and serologic evidence of syphilis.

Meningeal Neurosyphilis

Once the spirochete has entered the body, it spreads with great rapidity. It may be found in the lymph nodes before the chancre is visible, and presently it appears in the blood stream as well. In about one-third of the cases, its entrance into the central nervous system is reflected first by an increase in the number of cells in the spinal fluid, then by positivity of the serologic reaction in syphilis, increase in protein and alteration of colloidal solutions. The cells encountered in the spinal fluid may include small lymphocytes, large lymphocytes, plasma cells and neutrophils. When invasion of the nervous system occurs, it usually has taken place by the end of the third year. As time goes on, invasion becomes less and less likely, and the possibility of development of neurosyphilis diminishes correspondingly. In general, it may be said that if the reaction of the spinal fluid does not become positive during the first three years of the disease, it will continue negative, which in turn indicates that neurosyphilis neither is present nor will occur. It also has been learned that the more severe the reaction and the longer its duration, the worse is the prognosis. Thus far these changes in the spinal fluid need not be accompanied by symptoms, a situation classified as asymptomatic neurosyphilis. In about one-third of these cases, however, symptoms do develop, and then we speak of symptomatic neurosyphilis.

Involvement of the nervous system is marked by edema, cellular infiltration, particularly lymphocytic, increase in connective tissue and the formation of granulomas, or gummas. These changes follow the various fissures of the central nervous system, invade the brain, cord and nerves and cause symptoms and signs in profusion that come and go. None of the nerves arising from the brain or cord is immune to involvement. Fever is rare but it may occur, and the signs are sometimes those of an acute meningitis. More often the course is chronic. Headache is very common.

There may be choking of the disks but even so, a spinal puncture must be ventured to decide the issue. Involvement of the ependyma may close the aqueduct and lead to hydrocephalus. The dura mater may become enormously thickened, may then constrict both nerves and cord, most commonly, but not always, in the cervical region. Such a hypertrophic pachymeningitis then results in pain, sensory-motor paralysis of the upper extremities and a spastic paraplegia of the lower extremities. Spinal puncture usually reveals obstruction of the subarachnoid pathways. Gummas, though now rarely large, may form at any place and produce the picture of a tumor of the cord or of the brain. It is needless to say that a disease possessed of such vagaries in space and time may simulate almost any organic disease of the nervous system. Perhaps the most serious mistake that can be made, and made very easily, is to overlook the fact that a psychoneurosis, too, may be simulated. Also, it must not be forgotten that the serologic tests may give negative results and that the disease may progress in spite of treatment.

We must not leave the impression that the grand headings, "dementia paralytica," "tabes dorsalis" and "meningovascular neurosyphilis" are crystalline entities. In each the picture may be incomplete or atypical, and parts of all may be interwoven.

In 1851, Romberg exclaimed regarding the treatment of tabes, "There is no prospect of recovery of patients of this class; the fatal issue is unavoidable; the only consolation that can be offered to those fond of existence is the long continuance of the disease. It is but common humanity to inform him at once that therapeutic interference can only injure, and that nothing but the regulation of his diet can retard the calamitous issue." This was a grave pronouncement and, in a large measure, it would still apply, were it not for the effective treatment now available and the fact that early diagnosis is the rule.

Treatment

The treatment of neurosyphilis depends on three factors: (1) type of neurosyphilis encountered, (2) degree of activity of the cerebrospinal fluid and (3) general condition of the patient. All three factors must be evaluated together before a decision is made as to the treatment which will be most beneficial to the patient. As a rule, the general condition of the patient determines whether he should be inoculated with malaria or whether hyperpyrexia should be induced otherwise, and whether or not penicillin should be administered alone or in conjunction with the fever therapy. For instance, a patient with severe diabetes, hypertensive heart disease or cirrhosis of the liver should not be given fever therapy no matter how active may be the cerebrospinal fluid or how severe the clinical manifestations of his neurosyphilis.

Classification of Neurosyphilis.—Neurosyphilis may be of the following classes:

Asymptomatic
Meningeal
Meningovascular
Vascular
Tabes dorsalis with or without optic atrophy
Dementia paralytica with tabes dorsalis (taboparesis)
Dementia paralytica (paresis)

Special types:

Gumma of spinal cord or brain
Amyotrophic lateral sclerosis
Erb's spinal spastic paralysis
Epilepsy
Transverse myelitic syndromes (usually due to vascular occlusion or gumma)
Nerve deafness
Optic atrophy without tabes dorsalis, primary or secondary to neuroretinitis

In practically all instances a diagnosis of neurosyphilis must be confirmed by an examination of the cerebrospinal fluid, and in all patients with a persistently positive serologic reaction for syphilis or a history of syphilis, the cerebrospinal fluid should be examined for neurosyphilis.

Characteristics of active spinal fluids are summarized in Table I.

An arrested or inactive type of cerebrospinal fluid is characterized by a normal cell count and a normal protein value, but there may be degrees of positivity of the complement-fixation reaction and the colloidal gold test may show persistent reactions of the first or middle zone.

Penicillin.—Whether penicillin is to be administered alone or in conjunction with fever therapy, the total dose in one course of treatment should not be less than 6,000,000 Oxford units. In order to avoid a serious Herxheimer reaction, as may be expected in cases of general paresis, optic atrophy or gumma of the spinal cord or brain, the first twenty-four injections of penicillin should

be of 5,000 Oxford units each administered every three hours, followed by injections of 50,000 to 60,000 units every three hours until the total amount desired has been given. Penicillin is used preferably in the form of procaine penicillin, 300,000 units being given once or twice daily until the total dose of 6,000,000 units has been administered in instances in which Herxheimer effects are not anticipated. Other types of penicillin are used as well. Aqueous solutions of penicillin were given formerly in doses of 50,000 units every three hours for 120 injections or in doses of 60,000 units every three hours for 100 injections. Calcium penicillin in peanut oil and beeswax is also used but is being replaced by procaine penicillin. Other types of penicillin are on the way; however, there is not sufficient information to know their efficacy as yet. If penicillin is to be administered in conjunction with fever therapy, its administration should be started at the time fever begins unless a Herxheimer reaction is expected, when administration of penicillin should be started six to seven days in advance of the febrile period. Penicillin alone will reverse to normal or near normal spinal fluids of which the cell count is high. In the presence of clinical signs and symptoms, when a trial with penicillin fails to produce clinical improvement, fever therapy should be considered.

TABLE I. CHARACTERISTICS OF THE CEREBROSPINAL FLUID WHEN SYPHILIS IS ACTIVE

Group	Leukocytes per cubic millimeter	Total Protein, mg. per 100 c.c.	Complement Fixation	Colloidal Gold
I	6 or more	Normal or elevated	Negative	0000000000 to 3221000000
II	6 to 150 or more lymphocytes	Elevated to 120	Positive with 0.5 to 1.0 c.c. of fluid but not with smaller amounts	Any type, 0012321000 to 3221000000
III	50 to 200 lymphocytes, 0 to 25 polymorphonuclear cells	Elevated to 200	Positive with weak dilutions	5554310000

Fever Therapy.—Fever can be induced mechanically (Kettering hypertherm), by inoculation with malaria (Plasmodium vivax, Plasmodium malariae) or by intravenous injection of typhoid vaccine. In cases of neurosyphilis, either mechanically induced fever or malariotherapy is suggested, but treatments should be given by those especially trained in the use of these agents.

The best results are obtained if a fever of more than 103°F. (oral temperature) is allowed for fifty or more hours. These hours of fever are obtained most often after the patient has had eight to ten paroxysms of malarial fever.

It is imperative that patients who receive fever therapy be observed closely for the development of complications. If there are signs of cardiovascular collapse, manifested by persistent hypotension (systolic pressure less than 90 mm. of mercury) and persistent tachycardia, pulmonary edema and myocardial failure, fever therapy should be discontinued permanently. Malaria fever therapy produces some hepatic damage in practically all cases, but such damage is usually not of serious significance. If the icteric index rises steadily and jaundice is present, the treatment should be discontinued permanently. Moderate degrees of anemia are common, especially in cases in which the patient has malaria; if severe anemia (hemoglobin value less than 7.0 gm. per 100 c.c. and an erythrocyte count less than 2,500,000 per cubic millimeter of blood) is present, permanent discontinuance of fever therapy is necessary. Other complications, such as nephritis, pneumonia, manic states and cerebrovascular accidents, are uncommon but also necessitate discontinuance of fever treatment. Many patients become physically tired, weak and "washed out" with malarial therapy, and these individuals may obtain temporary remission of fever from administration of 75 to 150 mg. of thio-bismol (sodium bismuth thioglycolate). For permanent termination of malaria, atabrine (quinacrine hydrochloride) or chloroquine (7-chloro-4 4-diethylamino-1-methylbutylamino quinoline diphosphate) is administered.

The first evidence of improvement in the cerebrospinal fluid after treatment with either penicillin or fever is lowering of the abnormal cell count. This is followed shortly by decreasing values for protein. Abnormal complement-fixation and colloidal gold reactions may persist for months and years.

Specific Types of Neurosyphilis.—Suggestions for treatment of specific types of neurosyphilis, to be considered only as a guide at the start of treatment, are included in Table II. There are exceptions in every class of neurosyphilis. The cerebrospinal fluids of patients who have vascular neurosyphilis or gummas which involve the spinal cord and brain frequently are normal, and thus the status of the cerebrospinal fluid cannot be used as a guide to treatment. The greatest exceptions to the suggested treatments occur in the unusual instances of neurosyphilis in which the disease is clinically progressive and the cerebrospinal fluid is normal or nearly normal. In these cases penicillin should be administered and fever should be induced concurrently; however, the results of such treatment or of any treatment are generally poor.

Patients with an arrested or inactive type of spinal fluid should also receive special consideration. They are usually tabetic patients who may or may not have received previous treatment. It is doubtful that further treatment will improve the status of the cerebrospinal fluid, but a course of penicillin often will result in an increased sense of well-being and a gain in weight, together with a decrease in severity and frequency of gastric crises and lightning pains. The tonic effect of penicillin seems to be noted in most cases of neurosyphilis, regardless of the type.

TABLE II. SUMMARY OF TREATMENT OF SYPHILIS IN RELATION TO DIAGNOSIS AND CONDITION OF SPINAL FLUID

Diagnosis	Cerebrospinal fluid, group	Penicillin, units	Fever
A. Asymptomatic	I and II	6,000,000	No
	III	6,000,000	Yes
B. Meningeal	I, II and III	6,000,000	No
C. Meningovascular	I and II	6,000,000	No
	III	6,000,000	Yes
D. Vascular	Frequently negative	6,000,000	No
E. Tabes dorsalis (without optic atrophy)	I and II	6,000,000	No
	III	6,000,000	Yes
F. Tabes dorsalis (with optic atrophy)	I, II and III	6,000,000 to 9,000,000	Yes
G. Dementia paralytica with tabes dorsalis (taboparesis)	I and II	6,000,000 to 9,000,000	No
	III	6,000,000 to 9,000,000	Yes
H. Dementia paralytica (paresis)	I and II	6,000,000 to 9,000,000	Yes
	III	6,000,000 to 9,000,000	Yes
I. 1. Gumma	Frequently negative	6,000,000	No
2. Amyotrophic lateral sclerosis	I, II and III	6,000,000 to 9,000,000	No
3. Erb's paralysis	I, II and III	6,000,000 to 9,000,000	Yes
4. Epilepsy	I, II and III	6,000,000	No
5. Transverse myelitis	(See C, D and I, 1)		
6. Nerve deafness	(See C, D and I, 1)		
7. Optic atrophy	I, II and III	6,000,000 to 9,000,000	Yes

Observation and Further Treatment

The patients should be re-examined four to six months after the end of treatment with penicillin alone or with penicillin in combination with fever therapy. Such an examination should include the serologic tests for syphilis, re-examination of the cerebrospinal fluid and physical examination to determine the patient's neurologic and general status.

In cases in which the condition has responded favorably to treatment, the following effects are evident: the tonic effect of penicillin already noted, together with steady diminution of the more specific symptoms such as gastric crises, lightning pains, convulsions and mental aberrations. The spinal fluid exhibits improvement chiefly in regard to the cell count and the values for protein. The complement-fixation reaction and the abnormal curve of the colloidal gold test do not indicate response as soon as do the manifestations just mentioned. These latter two tests ordinarily are not considered to be valuable signs for or against the need of further treatment.

If there has been a satisfactory clinical response and if the cell count and the value for protein have become or have approached normal, no further treatment need be given at the time. The patient should then be re-examined at intervals of six months for the next two years and yearly there-

after. If the cerebrospinal fluid has been normal or has exhibited the arrested type of formula for two years after treatment, further examinations of the cerebrospinal fluid need not be made unless there is a clinical or serologic relapse.

In cases in which response to treatment has been unfavorable (1) there is no clinical improvement in the symptoms in which improvement should be found, (2) the symptoms are of increased severity or (3) in the instance of asymptomatic neurosyphilis, evidence of symptomatic neurosyphilis develops. The cerebrospinal fluid exhibits the same cell count and concentration of protein as it did before treatment, the values are increased or there is slight but insignificant diminution of cell count and concentration of protein. The lack of beneficial response to treatment may be shown either in the clinical symptomatology or the cerebrospinal fluid or both. If response to treatment is unfavorable, the treatment should be repeated.

Further Treatment.—For those patients originally treated with penicillin alone, another course of penicillin combined with induced fever should be given if the general condition of the patient permits use of hyperpyrexia. If the patient originally had treatment with fever and penicillin combined, subsequent therapy is ordinarily limited to further courses of penicillin. In exceptional instances more fever therapy can be given.

Patients who respond unfavorably should be investigated at intervals of four to six months, and treatment should be continued as long as clinical symptoms progress and the cerebrospinal fluid remains active, as shown by elevated cell counts and abnormal values for potein.

Summary and Conclusions

The diagnosis of neurosyphilis has been discussed with consideration of the broad clinical types of neurosyphilitic involvement. Some of the interesting historical descriptions and impressions of the early authorities are quoted.

The importance of correlating (1) the type of neurosyphilis, (2) the activity of the cerebrospinal fluid and (3) the general condition of the patient before determining therapy is stressed.

A table suggesting therapeutic procedures with penicillin alone or penicillin combined with fever is given, but this should be used only as a basic guide for the therapeutic requirements of an individual patient.

BIRTHS REMAIN HIGH IN 1948

The second largest number of births in the history of this country occurred during 1948. This information, released by Federal Security Administrator, Oscar R. Ewing, summarized data prepared by the National Office of Vital Statistics of the Public Health Service.

The number of live births registered during 1948 was estimated at 3,559,000 or only about 4 per cent below the all-time high of 3,699,940 for 1947. Of even greater significance are the figures which take into consideration the unregistered births. The total number of births (registered and unregistered combined) was estimated at 3,715,000 for 1948 and 3,876,000 for 1947. Only eight years earlier, in 1940, the last pre-war year, the figure was little more than 2½ million (2,558,000).

The 1948 estimated birth rate of 24.4 per 1,000 population was about 5 per cent below the final rate of 25.8 for 1947, but exceeded the 1946 rate (23.3) by almost 5 per cent. (These rates and all other figures which follow are based on registered births.)

Striking changes occurred in the birth rate during the postwar period 1946-48. Demobilization beginning in the last half of 1945 was reflected by extraordinarily high birth rates in the latter part of 1946. In 1947 the monthly rate declined from the peak rates experienced at the end of 1946 but was nevertheless at a high level throughout the year. The rates in the last half of 1948 were significantly higher than in the earlier months and about equalled the rates in the last half of 1947. When the monthly rates are corrected for "normal" seasonal variation, the rate changes during this period are further clarified.

Final 1947 birth rates on a residence basis are now available for each State and the District of Columbia. The State rates ranged from a high of 37.2 (per 1,000 population present in area) for New Mexico to a low of 22.8 for New York. The birth rate for half of the States and the District of Columbia fell within the range 25.0 to 30.0. The rates for fourteen States were below 25.0, while in ten States they exceeded 30.0.

The proportionate changes in the birth rates for each State between the last pre-war year, 1940, and 1947 show that fifteen States had increases of 50 per cent or more; fifteen increases of between 40 and 50 per cent; fourteen between 30 and 40 per cent; and four between 20 and 30 per cent. Greater proportionate increases were recorded in those areas which for many years have consistently had comparatively low birth rates.

DO WE KNOW WHERE WE'RE GOING?

E. H. O'CONNOR
Managing Director, Economics Society of America
Chicago, Illinois

BETWEEN the great things we cannot do and the small things we will not do the danger is that we shall do nothing.

On that premise I appear before you today in a sincere effort to arouse you to action, to urge you to recognize and understand the problem of progressive socialism which, if permitted to continue unabated, will eventually destroy our voluntary society and our free market economy.

Whether you realize it or not we are fast approaching socialization by taxation. We are just ten years behind England on the schedule planned by the designers of confusion who are bent on destroying the competition of private ownership. We have all been very smug and complacent. We have taken our freedom for granted. We have washed our hands of so-called "dirty politics." We have buried our heads in the sand while a small minority in our midst has been steadily undermining the foundations of our freedom for half a century. This blindness obscures the mind and causes the average business and professional man to be less perceptive and alert. The man who no longer grows in bone and muscle builds a fatty insulation not only around his middle but around his head. He is thickened against the acquisition of ideas, and the abstract principles over which the founders of the country labored and which must be understood for each to do his part to preserve liberty throughout the land.

Such, I believe, is the great issue of our time and this issue can be met if courageous men and women will now uphold private enterprise against collectivism in Federal, State, and local governments. Let us restore the American incentives to work, to "have and to hold"—the old rewards for producing more and better goods. Let us put a stop to the government's use of the money of taxpayers to compete against them—yes and above all—stop politicians buying votes with "Federal Aid" for such measures as governmental protection from the cradle to grave and socialized medicine.

The fabulous prosperity that has persisted throughout the country during the postwar era is beginning to produce a brand of economic thinking that America could very well do without. Fat pay envelopes and employment on a scale recently considered to be fabulous appear to be taking on the properties of an opiate that obscures facts and deadens the power of reason.

A feeling of exuberance and rose-tinted optimism is gaining headway and with it the adoption of policies and doctrines as nebulous as the illusions that produced them. Therefore, it is time to take stock in order to build a structure that will stand up under more stringent conditions.

A case in point is provided by the attitude of some federal payrollers and legislators toward a more comprehensive program of social security—a plan of government guardianship for everyone from the cradle to the grave. It seems we have an unlimited supply of reformers, humanitarians and would-be-managers-in-general who have a common notion that one has a duty to society, as a special and separate thing, and that this duty consists in considering and deciding what is good for other people. In their zeal they overlook the long history of man's struggle for freedom which clearly indicates that a part of the price he must pay for it is the willingness to assume a large measure of responsibility for his own well-being. Whenever men have endeavored to transfer their responsibilities to the shoulders of other fallible men calling themselves government, they have eventually reared a Frankenstein monster that has turned and devoured their political, intellectual and spiritual liberty. This earth was never intended to be a full and complete Utopia. The good Lord just didn't plan it that way. Didn't he say "Thou shalt earn thy bread by the sweat of thy brow?" That was not a primeval curse but a law of progress and any legislative scheme which trys to turn this law inside out will doom all to destruction. As we look back in our own history we recognize that struggle makes strength and no person's security can exceed his individual self-reliance.

Neither the insurance industry, the medical profession nor business in general have been sufficiently alert to the dangers of comprehensive national social insurance. The legislative and administrative history of social insurance throughout the world shows clearly that it is impossible to

---

Address given before the Ramsey County Medical Society, the Hennepin County Medical Society and other interested groups at joint meetings held in Saint Paul, December 6, and Minneapolis, December 7, 1948.

Mimeographed copies of this address may be obtained upon request through the office of MINNESOTA MEDICINE.

accept one part of social insurance without ultimately falling prey to the whole scheme; that social insurance insidiously pervades the entire body politic like a cancer, and that benefits bestowed as social insurance rights are purchased by surrendering human rights. In other countries legislation for national social insurance has always meant subjugation of the individual to the Government.

When Bismarck instituted the payroll tax and compulsory insurance, Prof. Adolph Wagner, his economic advisor, said "the plan was to raise revenue, control the people, and redistribute income." The state was to take over control of banking, insurance, communications and utilities. The workers were to be induced to agree to compulsory taxation and bureaucratic control in return for small social insurance benefits. In other words, the state bought the workers with small bribes and seized control.

Bismarck's "social" insurance laws were acclaimed as the "high water mark of German State Socialism" sixty years ago, but they were laws embracing political and economic devices, rather than genuine social measures. The point has been well made that social insurance is neither social nor insurance.

Unfortunately, at the present time, there are many persons—sound citizens, trusted members of the community—who believe that a "little social security" like a "little inflation" is good for the country. But the question arises whether one can take a "little social security" without desiring larger amounts. The trouble with social security is that small doses develop an insatiable craving for larger doses. No social security program, however undesirable, has failed to expand, and in its expansion it penetrates the entire economy ever more deeply. The triple curse of social security is the spiral of political promises, the weight of bureaucratic conflict, and the crushing burden of taxation.

I believe I can make the statement, without fear of contradiction, that a large segment of our people have been fast asleep and completely unaware of the octupus-like movement of government compulsory insurance both at the state and federal levels. We bury our heads in our daily tasks and leave our tail feathers exposed to the skirting gales of political controversy. We all have a great deal at stake in the movement to expand our social security act. Not only should our interests be motivated with the desire to keep and maintain our business free of further governmental interference, but greater than that we must be ever alert to preserve the principles of our competitive voluntary enterprise system, which the so-called "intellectual" in his supreme conceit would destroy.

It is of the greatest importance to realize at this time that every effort is going to be made to do three things in the Social Security field, namely: (1) expand Social Security coverage for old-age and survivors' insurance to cover presently excluded groups and at the same time to increase the taxes and raise the taxable wage level from $3,000 to $4,800; (2) introduce, and if possible, enact legislation for federal cash sickness benefits under a Federal-State arrangement comparable to the arrangement now existing in connection with employment programs; and (3) introduce, and if possible, enact legislation for cash disability benefits to be administered by the Federal Government as a part of the Old-age and Survivors' Program.

The strategy of the Federal Government and of non-federal advisors is to extend the coverage to all or nearly all the population in a field which is considered non-controversial, namely, old-age and survivors' insurance. The effect of this extension of coverage has powerful repercussions when you come to later programs for additional benefits. It means that such benefits will then automatically apply to the population which has already been brought under the Social Security umbrella. Few persons see that once you accept the principle that governments, either Federal or State, have the primary responsibility to provide support for individuals who are out of the labor market, either permanently because of old age or temporarily because of unemployment, you will ultimately be compelled to accept all the major Social Security programs. Thus, logically, you will be compelled to accept the cash sickness benefits program because unemployment due to sickness is akin to unemployment due to lack of a job. Similarily, unemployment due to permanent disability is akin to unemployment due to old age; and, consequently, that risk must be covered by the Government. But once you have set up Government insurance programs to pay cash benefits during periods of temporary sickness or of permanent disability and once you have set up trust funds for those programs, you will

inevitably be driven to accept a Government medical care program not so much for the benefit of the sick and disabled as to protect the respective cash benefits insurance funds. It will be argued that the majority of workers are not able to pay for doctors when they are sick and that, consequently, they will be out of work longer than will be necessary and will be drawing sickness benefits. It will also be argued that many persons who will leave the labor market on the ground that they are permanently disabled and will, therefore, draw cash benefits as long as they live, might be restored to a certain degree of earning capacity if only the Government would provide the medical care they need. If that unhappy day ever arrives, a goodly proportion of the physicians of this country will devote their entire time, not to improving the health of the people, nor caring for the sick, but simply carrying out the social insurance task of certifying patients for cash benefits during sickness and permanent disability.

The adoption of a national system of sickness insurance would involve the extension of federal control into the lives of nearly every American in a measure unprecedented in the history of the nation. It would extract taxes from every pocketbook, and of necessity swell the proposed health, education, and security department into one of the biggest and most powerful government departments the country has ever known. In short, it would be straight state socialism with ultimate power over all the people vested in the Federal Government.

President Truman has never presented a budget to the American people on the costs of his social security proposals yet his program would add billions to the cost of social insurance. Sweeping increases in benefit payments, the extension of coverage to upwards of 20,000,000 additional persons and the inauguration of new types of social insurance are provided in the President's program. To finance this wholesale expansion of social security an immediate sharp increase in Federal payroll taxes and eventual higher state unemployment insurance levies will be required. What the social security proposals mean to business is illustrated by the proposed changes in the Federal payroll tax for pensions. The tax rate would be raised from 1 to 1½ per cent and the impost would be made to apply to $4,800 instead of $3,000 of earnings. For the average employer, this would mean an increase of 60 to 70 per cent in Federal payroll taxes. At the same time, extension of coverage would make numerous additional employers subject to the tax. Business is on the eve of a period of intensified competition and narrowing profit margins. A jump in social security taxes may seem bearable at the moment, but when profits decline they will become a grievous burden.

The far-reaching consequences of social security are well illustrated by its impact upon savings and investment. The federal trust funds are now collecting $2½ billion more than they pay out in benefits. This vast sum is 25 per cent of the annual liquid savings of the people as estimated by the Securities and Exchange Commission. This large segment of the nation's savings is not available for investment in private enterprise. It must be placed in Government securities. Do we want to divert the larger part of the liquid savings of the American people into Government funds that can only buy Treasury Securities? This is one of the many related questions to which Congress has given little consideration. It is one of the more powerful reasons for further unbiased study, and at least obtaining the opinion of the American people before Congress is asked to vote upon the President's proposals for a sweeping expansion of the social security program.

Lincoln is quoted as saying "The legitimate object of government is to do for a community of people whatever they need to have done but cannot do at all or cannot do so well for themselves in their separate and individual capacities. In all that the people can individually do as well for themselves the government ought not to interfere." Let us see what the people of this Country have done in protecting themselves against the important hazards of life.

According to a recent study, life insurance protection in force in private companies now exceeds $200 billion, covering more than 75,000,000 policyowners with total assets of over $52 billion. According to the Health and Accident Underwriters Conference more than 45 million persons were covered under some form of accident and sickness insurance at the end of 1947 with a total annual premium volume of over $800 million. To this may be added many more millions for hospitalization coverage through Blue Cross and protection by prepayment medical plans.

Roughly if we start with the basis of pro-

tection built up over a period of more than one hundred years by private insurance companies and organizations and add to this the savings established through savings banks, savings and loan associations, real estate, investments and by the purchase of war bonds we can total up resources committed to the protection of our people, amounting to over three hundred billion dollars, which, I submit to you, is an amazing figure. Of greater significance is the unhampered opportunities which made it possible to accumulate so large a reserve. Any tampering with these opportunities may have fateful consequences. It would probably be difficult to retain thrift, ambition, and industry under a comprehensive system of compulsion such as social security. It is difficult, therefore, to see how it can be argued that present facilities and opportunities are so inadequate as to call for an entirely new system having economic and political implications which can destroy America as a land of freedom and opportunity.

The advocates for government compulsory sickness compensation and medical care are subjecting the public to a barrage of twisted facts which distort the situation. They argue that the statistical sample examined by the draft boards in the last war was representative of the country's young adult male population. That is not true as was proven by Dr. Maurice Friedman in his testimony before the Senate Subcommittee on Health. In the first two years of the war, the draft boards examined about ten million men and rejected 36 per cent of them. But during the same period, over two and one-half million enlisted voluntarily. If these men had gone through Selective Service, the over-all rejection rate would have dropped automatically from 36 to 28 per cent.

Then of the manpower that remained after voluntary enlistments, more than one-third received deferments because of essential occupation or dependency. In other words, Selective Service examinations were limited to those young adult males who did not volunteer and who did not rate deferments. That's scarcely a true cross-section.

In breaking down the "why" of draft rejections we find that 22 per cent of the conditions were beyond the province of the medical profession—illiteracy and mental deficiencies; 47 per cent of the conditions were not preventable or remediable—heart ailments, defective vision, amputations; 3 per cent were possibly preventable such as tuberculosis; 11 per cent were not preventable but correctible—tonsils, kidney stones, varicose veins, hernias; 5 per cent of the conditions were preventable and correctible—otitis media, teeth, hearing. From this breakdown it is apparent only about 19 per cent of draft rejections could have been influenced by medical care and then we must assume that the individual would have sought medical attention, that he would have accepted the doctor's recommendations, and that the treatment would have been 100 per cent effective in every instance. Any statement that one-half to two-thirds of such defects are preventable or remediable is utterly false and further it proves that selective service statistics have no place whatsoever in any honest discussion of the deficiencies existing in our medical services or the need for compulsory government sickness compensation.

Now the same individuals are emitting loud wails over the dire implications of the present draft rejections. The figures show that in the nation's ten largest cities, rejection of young men called up for pre-induction examination has run, on the average, at 62 per cent. The rate ranged from a high of 87.5 per cent in New York to a low of 37 per cent in Los Angeles. In Chicago, the nation's second largest city, it was 85 per cent. Although Selective Service Director Lewis B. Hershey put no such interpretation upon them, these figures were immediately seized upon by the national health insurance crowd as evidence that our human resources were in terrible shape.

Actually, of course, the rejection data do not prove anything of the sort. The men called up during the first few weeks of the draft were in the twenty-four to twenty-five year-old groups. Veterans are exempt from the new call, so that those examined were largely those who were rejected for service in World War II on physical or mental grounds or because they were engaged in essential work. Among them were large numbers of 4F's who would be accepted now only if they had overcome the handicaps which brought about previous rejection. Director Hershey says the results are just about what draft officials expected.

I think you will agree that the basis on which military rejections are made does not suggest that we are rapidly going to pot physically and

mentally. As any actuary will tell you, quite the reverse is true: the average age of the population is increasing rapidly—so rapidly in fact that it will soon be a social security problem all by itself. Recently the Federal Security Agency experts took a look at death rates in this country and came up with data showing life expectancy today to be greater by about twenty-four months than it was a brief seven years ago. The average American born in 1948 can expect to be here in 2015, regardless of sex or race. Yet while improved medical care is prolonging life the birth rate has declined. At the turn of the century only about 3 million Americans were sixty-five or older. By 1940, their number had increased to 9 million. When 1960 rolls around citizens in the sixty-five or over group will number 14,000,000; at the century's end the figure is expected to be 21,500,000 or more. If the F.S.A. figures on longevity and births are reasonably reliable, a security system that would provide even more subsistence for 21,500,000 men and women over sixty-five would be an intolerable burden for the steadily decreasing number of employable citizens who would have to be taxed to support not only social security but all other government activity. It might be exercising good judgment to permit the aged to continue working to age seventy instead of planning for social security pensions at sixty-five or sixty, in view of our steadily increasing rate of life expectancy which is now sixty-seven years.

Now let us review a few pages of history: Bismarck, the Iron Chancellor, introduced compulsory social security in Germany, not as a social measure, but as a means by which he sought to stem the rising power of the labor party and to retain power in conservative hands. He made the state responsible for the industrial masses, protecting them against fear and want. The only price the masses seemingly had to pay was to protect the Hohenzollern dynasty against the liberal opposition, by voting the funds for a strong central government. With the introduction of State socialism, German liberalism was finished. The Government gave "benefits" to labor, industry, farming, banks. Liberal arguments could not defeat these vested interests.

In 1911, Britain adopted the German system of old-age and sickness insurance. By 1924, Britain was taking the lead in socialization, "insuring" workers against unemployment before the German Republic did. Lloyd George had transformed the Liberal Party into a middle-class Socialist Party. It was, of course, the end of the liberals. The Labor Party could promise more. As the English turned to the philosophy of statism, made glamorous by Prussian professors and generals, as government bureaus and cartels and other vested interests grew, the English lost their independence to the State.

In the last sixteen years, we too have seen business, education, labor and local government in this country become accustomed to gifts from the Federal Government. Our danger is not from a dramatic abandonment of liberalism, but from a leaking away of principles, a little compromise, with this spending program and with that, until today both political parties are as completely enmeshed in its commitments to mass supporters as were ever the New Dealers.

There are some people who quibble over calling compulsory sickness insurance "socialized medicine"; some who claim that a little socialism won't hurt. Call it what you will, but you can't be a little bit socialistic any more than you can be a little bit pregnant. Either you are or you aren't. Compulsory sickness insurance can lead to only one result: socialization of medicine and eventual socialization of all fields of endeavor. Mr. Justice Brandies who in his day was considered an extremely liberal thinker said "experience should teach us to be most on our guard to protect liberty when the government's purposes are beneficient."

Here it might be well to give some consideration to the cost of a comprehensive system of social security. We know from experience with foreign systems that the costs always exceed original estimates. Taxes rise. In Germany, we find that the financial cost of social insurance increased more than one-hundred times over a period of less than fifty years; in Great Britain more than seventy times in less than forty years; in Canada more than twelve times in a little over twenty-five years; in New Zealand it doubled over a short period of ten years.

In our own country we find that the ultimate cost of a comprehensive system of social security by compulsion would be so great that it might require each gainfully employed person to work ten weeks at forty hours each—a total of four hundred hours a year, or more than 25 per cent of an annual work year—just to pay for social security. The ultimate cost of the new British system has been estimated at 24 per cent of gross

wages. This will give you an idea of the importance of the financial cost of social security. Without exaggeration it may be stated that no system of social security in any country has ever remained as small or as isolated as contemplated originally. Invariably, it has become a snowball making for greater cost, higher rates, wider coverage.

Labor's major interest in social security and governmental welfare programs dates back to the Wagner Act of 1935 which gave tremendous impetus to union organization. Members flocked to join. Gradually, the unionization process became more difficult, especially as unions worked deeper into the mass production industries. It became necessary to stage hard-fought organizational campaigns. These met not only with employer opposition, but also with worker inertia. New programs had to be devised, new goals set forth. Union leaders began to turn to government social security and medical care programs. They call for a broadening of social security coverage to encompass virtually all employes in the country, for new types of benefits, and for increased benefits. Together with the union drive to attain greater benefits from private employers, these demands foreshadow a future development in labor thinking which will seek to tie in such private program directly with federal security laws.

In Germany, labor thought it could control its social program and ended up by being controlled by ruthless dictatorship. In Russia, labor thought it could control its own destiny and ended up in a monopolistic economy. In New Zealand, the predominance of labor resulted in a socialistic form of government and economy. In Great Britain, labor which is chiefly responsible for the social security program, may feel again that it will be able to retain political control. And again, if history repeats itself, as it so often does, labor may see its ends defeated by the trend toward a monopolistic form of government. What seems to be overlooked by labor in this country is that when these social security programs cover the entire population, everyone will be up to his neck in compulsion and taxes. Once completely under Government control, labor will go the way of labor in other countries.

Many persons had high hopes for what might be accomplished by this program of social security. Few foresaw the advent of a vast Federal bureaucracy that sprang up almost overnight and subsequently turned into a powerful pressure group, demanding expansion of the program, higher taxes and more power. Do we want more forms, more regulations, more reports and more taxes?

To the businessman I urge you to analyze the whole social security program and ask yourself if you want any more of it. To the doctors and dentists I say "If you cannot see that there is a three alarm fire in your professional abode at the present time, you are likely to find yourself out in the cold staring at the ashes of what was once a beautiful practice and a free existence."

In closing I will read a statement made last year at Bogota, Chile, by a member of our State Department, Dr. Charles G. Fenwick, who registered a strong protest against the principles which had been proposed in the form of an inter-American Charter of Social Guarantees. He said:

> "What is needed today is a clarification of the objectives which we have in view in legislating for the protection of the workers. *The tendency of the present day is to make man a mere cog in the great machine of the state. In order to obtain security he must surrender liberty. In order to get protection against the industrial machine, which destroys his human personality, the worker must have recourse to the state; and the state then tends to become his master, substituting one form of slavery for another.* I could wish that the Charter might reaffirm the ideal of a free man, working under free conditions, paid a just wage which would enable him to support his family and to own his own home under conditions of dignity and security. *The liberty of the individual is being lost in the huge size of labor unions, in the dictatorship of industrial combinations, and in the all-comprehensive legislative authority of the state.* Our problem it seems to me, is to formulate a philosophy of social relations, to show the world how the security of the worker can be obtained without loss of his liberty."

VACANCIES IN MEDICAL SERVICE CORPS

The Army Medical Service Corps still has a number of vacancies in the grades of 2nd and 1st lieutenants in the following specialties: bacteriology, biochemistry, parasitology, serology, entomology, nutrition, toxicology, industrial hygiene, industrial hygiene engineer, optometry, psychiatric social worker, clinical psychology and sanitary engineer, under the provisions of Department of Army Circular 210 dated July 14, 1948.

Although most of the provisions of Circular 210 were suspended as of February 15, 1949, pending completion by the Department of the Army of a study of remaining requirements, applications for reserve commissions in most grades are still being accepted by the Medical, Dental, Veterinary, Nurse, and Women's Medical Specialist Corps, as well as by the Medical Service Corps for appointment in the grades of 2nd and 1st lieutenants.

BENIGN STRICTURES OF THE BILIARY PASSAGES

LAWRENCE M. LARSON, M.D., Ph.D. (Surg.) and JOHN H. ROSENOW, M.D., M.S. (Surg.)
Minneapolis, Minnesota

BENIGN strictures of the biliary tract constitute a very serious problem in the field of surgery. The patient suffers from a chronic and most distressing ailment which with the best of treatment carries a disturbingly high morbidity and mortality. Too, this is a condition in which bacteria, viruses, constitutional tendencies, inner conflicts, or acts of God play very little of an etiological role of primary significance. Here the hand of man, the surgeon, in fact, is usually causative, which renders this problem of first importance to all who undertake surgery of the gall bladder and bile ducts. It is the purpose of this presentation to discuss briefly the causes and prevention of such strictures, along with a few words about the general disease picture and its care, to present some of the more recent surgical concepts and experiences in the treatment, and to report a case in which repair of a stricture was effected with the use of a vitallium tube.

Etiology and Prevention

Flickinger and Masson, reporting a summary of 188 cases, pointed out that in 181 (96 per cent) cholecystectomy had been performed, and in five other cases some other biliary operation had been done, leaving only two patients without a history of biliary operation of some sort. In not all of these, of course, was it possible to determine definitely that actual trauma to the ducts was the etiological factor. In about 12 per cent of their cases a very extensive chronic obliterative cholangitis was found. Whether or not this condition followed a previous injury was impossible to tell, but in one patient in whom it was definitely known that the common duct had been injured, just such an extensive obliterative inflammatory process was found. In Cattell's series of 123 patients, operative injury was thought to have occurred in 80 per cent of all cases. Other authors (Cole et al, Walters and Lewis, Walton, and Eliot) give figures approximating these, namely, that from 75 to 90 per cent or more of cases are directly related to previous operation. Agreement, then, is quite general that trauma to the ducts at the time of biliary tract operations, usually cholecystectomy, is by far the most common cause of these strictures.

The actual incidence of strictures of the biliary tract is very difficult to determine with any accuracy. It would seem, however, from the increasing number of reports in the literature that the incidence is definitely growing. Cattell stated that in over 5,000 gall-bladder operations at the Lahey Clinic, only one operative stricture had been produced. This is the only statement we have been able to find in the literature where a figure is given for the actual incidence. All articles consulted, however, agree that this type of case is being seen with increasing frequency at the various medical centers. By far the best treatment of the condition is prevention, where a few extra moments of care, patience and diligence may save the patient untold misery, financial burden and possibly his life.

At the risk of appearing somewhat elementary, we wish to re-emphasize some of the points in the technique of cholecystectomy, because neglect of these principles can easily lead to trauma to the biliary tract, resulting in stricture. In discussing benign stricture, Walton aptly points out that one great principle of surgery especially applies here, that no structure in the human body must ever be divided until it and its immediate surroundings have been clearly displayed. Further points which deserve reiteration are these:

1. Safety in gall-bladder surgery is strongly dependent on good exposure, which in turn is a result of adequate relaxation of the abdominal wall, proper placement and length of incision depending on the habitus and degree of obesity of the patient, and on walling off and retraction of the adjacent organs.

2. The presence of acute inflammation may render recognition of the anatomic relationships difficult or even impossible, and may also render the tissues much more friable. It is generally agreed that cholecystostomy is not nearly as satisfactory a procedure from the curative standpoint as cholecystectomy, but it may be far more preferable to drain the gall bladder than to run the risk of injury to the ducts. In the presence of

Presented before the MacLeod County Medical Society, Glencoe, Minnesota, September 16, 1948.

acute inflammation a tie on the cystic artery may cut through repeatedly. In such cases, a hemostatic clamp can be left on, the wound closed around it, and the clamp loosened and removed in four or five days.

3. Perhaps one of the most frequent causes of trauma to the ducts is the presence of hemorrhage that is difficult to control. A spurter, usually the cystic artery, is divided, and immediately the depths of the wound fill with blood. Blind attempts to clamp the vessel will almost inevitably result in damage. If the ducts are damaged, it is a catastrophe of the most unfortunate type, for in finding the location of the bleeder it usually means that the hepatic duct will be clamped, and this type of injury is the most difficult to repair later. Digital compression of the hepatic artery in its course anterior to the foramen of Winslow, between the thumb and forefinger of the surgeon or first assistant, will control the hemorrhage; the field can be wiped dry, and the bleeding vessel found and accurately controlled.

4. If the gall bladder is pulled upon and is relatively mobile, the common duct may be drawn up in a loop, or "tented" in such a way that its first part runs in line with the cystic duct and is mistakenly divided. This is especially prone to occur if this is not borne in mind when resection of the gall bladder is done from above downward, for then not only are the parts more mobile, but the field is obscured by blood escaping from the raw surface of the liver.

5. In many cases of cholecystitis, especially where there has been obstruction of the cystic duct, the gall bladder may become dilated and the inflamed Hartman's pouch cover and become adherent to the cystic duct. The common bile duct then appears to issue from the inner side of the pouch and is divided in the belief that it is the cystic duct. A very similar condition occurs if the pouch is still larger and is adherent to the common duct itself.

6. The very frequent occurrence of anatomic variations in the biliary ducts and their vascular supply must be kept in mind at all times. Abnormalities of the ducts and adjacent vessels have been reviewed in detail by Eisendrath, Flint and others, and their illustrations give an excellent idea of some of the difficulties arising from anatomic variations which may be encountered. For example, in 12 per cent of individuals there are two cystic arteries, both of which do not always arise from the right hepatic. In only 75 per cent do the cystic and hepatic ducts unite at an acute angle. In 17 per cent the cystic and common ducts pursue a parallel course for varying distances before they unite, and in 8 per cent the cystic duct makes a spiral twist around the front or back of the main hepatic ducts. These are only some of the more frequent variations. Others less frequent, while only rarely encountered, need to be met only once to give rise to disastrous results if too blind faith is placed in the rules of the "normal" anatomy of this region.

Another point that deserves mention is the matter of the indications for the cholecystectomy. Flinkinger and Masson found that in their series of cases of stricture of the ducts, cholecystectomy was not associated with the presence of gallstones in at least 11 per cent and possibly more. Traumatization of the ducts does not occur frequently, perhaps, but when it does occur, it is a real tragedy. The possibility of this dire complication should always be considered in evaluating the indications for cholecystectomy, especially in the absence of calculi, and should give the surgeon serious pause in considering the removal of the gall bladder.

Diagnosis

As to the diagnosis of these conditions, there is not usually much difficulty. Walters and Snell state that 99 per cent have either jaundice or an external biliary fistula. The cases fall into three major groups. There are those in whom jaundice develops quite promptly after operation, deepens and is constant. In another group, there is prolonged biliary drainage after operation, which may intermittently cease, during which cessation the patient becomes jaundiced and develops signs and symptoms of ascending biliary tract infection. In the third group, which is the smallest, the patients pursue a perfectly normal postoperative course, and then, after a period of months or even years, insidiously develop jaundice.

The preoperative preparation of these patients sometimes requires rather extensive effort and application on the part of all concerned. Every attempt must be made to evaluate the functional status of the liver and to restore it to as nearly normal as possible. In cases of long standing, the renal function may be impaired, and an effort should be made to improve this, although this is difficult; such impairment is of serious prognostic

import. In those patients with external fistulas, large amounts of electrolytes are lost in the biliary drainage, and these should be replaced by the liberal use of bile salts and sodium chloride by mouth. The refeeding of bile will be found a disagreeable and usually unsuccessful endeavor. The prothrombin time should be brought to normal or as nearly so as possible by the employment of large daily doses of vitamin K, with or without bile salts. The patients should be given a high carbohydrate, high protein, and low fat diet. Extra glucose should be provided parenterally, and a high carbohydrate diet, for the liver with good glycogen stores will withstand anesthesia much better. Large daily doses of the vitamins are to be used, especially thiamin and other elements of the B complex. Amino acid preparations and blood transfusions also may be necessary. In the seriously ill patients, those who have had multiple operations and long-standing jaundice with evidence of impaired liver function, a period of two or three weeks of preparation may not only be desirable but absolutely essential.

Treatment

It has been often repeated that most surgeons of wide experience probably have injured the common duct on at least one occasion. This occurrence is unfortunate, but even more unfortunate is the failure to recognize and treat the injury at the time. In a divided duct the upper end is easy to find, for it leaks bile. The lower end may be more difficult to locate but it should be sought for until found, for it will never be any easier to identify than it is immediately after injury. The two ends of the divided duct should be united by end-to-end anastamosis over a T-tube. Pearse and Cattell urge that the T-tube be brought out through a separate incision in the duct, so as to avoid trauma to the site of repair when the tube is removed. A duct that has been only partially crushed should be allowed to heal over a tube. If there has been extensive crushing or maceration, excision of the damaged area should be performed and end-to-end anastamosis effected.

If the injury to the duct is discovered during the postoperative period, unless the secondary operation is performed within a few days, it is better to wait until the inflammation and edema subside somewhat so that the surgeon may have pliable structures to deal with. Cattell feels that many of the failures in repair are due to too early intervention; if an external biliary fistula persists there is no urgency, as long as the lost electrolytes are replaced, and definitive surgery may be postponed at least three months. However if the patient develops a deepening jaundice, such delay will not be well tolerated, and operation should be performed earlier, in four to six weeks.

The multiplicity of methods that may be found in the literature for the treatment of benign strictures of the biliary tract amply testifies that there is no entirely satisfactory method, and no one method is applicable to all cases. There are certain general principles that underlie a successful repair regardless of the method. Accurate approximation of mucosa to mucosa should be sought, whether this be mucosa of duct to that of duct or to that of the gastrointestinal tract. This should be accomplished without tension. The leaving of a defect in the biliary duct should be avoided, for although this may give an excellent result initially, the formation of scar tissue in the defect, and its slow contracture, will inevitably result in reformation of the stricture. The repair should be performed over a tube or mold of some type, which should remain in place for at least several months. This maintains an adequate opening during the period of initial healing, and prevents contracture of surrounding fibrous tissue. If a T-tube is used and there is enough duct available, the vertical limb should be brought through a separate small incision in the duct. Any type of tube used in the repair should be anchored in the duct. Tubes which extend through the ampulla of Vater, or into the lumen of the gastrointestinal tract in those repairs where the duct has been anastomosed to the bowel, will usually pass in a short time, irrespective of type of anchorage.

The ideal, of course, is the restoration of the structure to as nearly normal an anatomical picture as possible. If sufficient duct remains above and below the site of the stricture, this condition can usually be fulfilled. Unfortunately those cases in which there is a small localized stricture are much in the minority. Cattell describes a procedure which has been employed at the Lahey Clinic in their most recent cases, by means of which distal duct can almost always be obtained. This consists of full mobilization of the duodenum and head of the pancreas, and dissection of the intrapancreatic portion of the common duct from its pancreatic bed, thus giving 2.5 to 5.0 cm. of distal duct with which to work. This is an ad-

mittedly formidable technical procedure, but apparently gives excellent results when feasible.

In cases where duct-to-duct approximation can be obtained, there is a good deal of disagreement as to the material of choice to be used as a supporting structure. Short rubber tubes of the Sullivan type have the following disadvantages: they are passed within a relatively short time and signs of an obstruction usually develop, although there are some exceptions; rubber usually begins to deteriorate in a year or so; rubber acts as a foreign body; there is a great tendency for the deposition of bile salts in the lumen of a rubber tube. Rubber T-tubes will, of course, not pass, but are open to the objections inherent in rubber. They have the advantage that if deposition of bile salts in the lumen does take place, the tube can be removed without the necessity of major surgical intervention. Pearse introduced the use of the preformed vitallium tubes. Their advantages are that they do not deteriorate, the vitallium is well tolerated by the tissues, does not act as a foreign body, and there is less tendency for the precipitation of bile salts. However, being of cast metal, they cannot be altered at the time of operation; they will occasionally pass. It was at first thought that the deposition of salts in the lumen would not be an objection, but it is evident from recent reports that this does occur. Once plugging has occurred, with the concomitant signs and symptoms of biliary obstruction, the tube must be removed by intra-abdominal exploration. In 1945, Pearse cited twelve cases, from a series of 208 collected cases, in which the tubes became secondarily obstructed, an incidence of 5.7 per cent. Neibling and Walters in September, 1947, stated that nine tubes had become obstructed out of seventy-four cases in which they had been used, an incidence of 12.3 per cent. One might speculate on a comparison between these figures, and the possible incidence of re-exploration necessary for strictures which reform after the removal of plugged T-tubes. It would seem that the vitallium tube is still worthy of a place in the armamentarium of the surgeon treating biliary strictures. A procedure which gives presumably satisfactory results in 94.3 per cent and 87.7 per cent of cases, respectively, is at least deserving of further trial, especially in a field where perfect results are notoriously difficult of attainment.

In this connection, the work of Best is of great interest. In 1938 he described a so-called biliary flush regime in the non-operative management of the overlooked or remaining common duct stone. Recently, he suggested the application of this regime to patients whose biliary tracts have been reconstructed over a vitallium or other tube, to prevent the formation of a precipitate in the tube, and remarks that if corrosion and encrustation do develop, the thinner bile makes an easier exit. He uses the three-day biliary flush once a month indefinitely, the details of which are given to the patient as follows:

1. Take three bile salt tablets (procholon or decholin) after each meal and at bedtime for three days.
2. Take one teaspoonful of magnesium sulphate in water each morning.
3. Take two tablespoonfuls of pure cream or olive oil before noon and evening meals and at bedtime for three days.
4. On the first day, place a nitroglycerin tablet (1/100 gr.) under the tongue before each meal.
5. On the second day, dissolve an atropine tablet (1/100 gr.) in a little water and take before each meal.
6. On the third day, repeat the nitroglycerin tablet as on the first day.

Naturally, if the choledochal sphincter mechanism is not functioning, as in the cases of anastomosis of biliary tract to gastrointestinal tract, it is not necessary to use the antispasmodic agents.

In cases where no distal duct can be obtained, or where there is little or no proximal duct, union between the biliary tract and the gastrointestinal tract must be effected if at all possible. Formerly, in those cases with little if any proximal duct, an external fistula was formed, and then this was later transplanted to the duodenum or intestine. The results were very disappointing, for contracture of the fistulous tract took place very frequently, with biliary obstruction. The procedure has been largely abandoned except as a desperate measure of last resort, where other more satisfactory procedures cannot be done. The usual procedure in union of the two systems has been choledochoduodenostomy or hepaticoduodenostomy. Cattell considers hepaticojejunostomy the method of choice. Allen described an ingenious method of repair, based on the Rous en Y principle, turning in the serosa and anastomosing it to the proximal duct, with a temporary catheter brought through the anastomosis. Cole et al utilized similar methods, but produced valves in the defunctionalized jejunum, by infolding it, to prevent reflux of intestinal content, which is thought

by many to be of serious consequence in the etiology of the cholangitis. The latter is a frequent complication.

Postoperatively, the treatment is similar to that of any biliary duct surgery. The parenteral administration of vitamin K is continued, with frequent checks of the prothrombin time, for at least one week. The fluid and electrolyte balance of the patient should receive the closest attention, and there should be free use made of blood transfusions. Large amounts of vitamins, especially thiamin and the B complex, are given. Drainage from the wound is commonly encountered, but if it has been possible to attain a satisfactory repair, this will cease within a maximum of two weeks. Bile salts are given during the first week. If a tube remains within the biliary system, the biliary flush regime mentioned by Best should be employed, and it is probably well to give a cholagogue as a daily routine in addition. If a T-tube has been used, this should be irrigated twice a day indefinitely, and it should be left in place six months to a year, preferably the latter.

Case Report

This individual is a married woman, forty-four years of age. Her family history and past history were irrelevant except for the following:

Eight or ten years ago she began to have indigestion from fatty foods, consisting of gas, belching and abdominal distention. This increased in severity and soon became associated with attacks of pain, colicky in nature localizing mainly in the right upper quadrant of the abdomen. She had never been jaundiced. In December, 1945, a laparotomy was done elsewhere for the purpose of removing the gall bladder, although she was never told exactly what procedure had been carried out. A few days after the operation she became jaundiced, the urine became dark and her stools clay colored. The jaundice gradually deepened and she states that her fever went to 104°F. About two weeks postoperatively the wound began to drain bile and she felt some better. The jaundice faded somewhat, and she was soon able to be up and about although the drainage of the wound was very profuse.

This patient was seen a year after the operation, and during this time the wound had drained continuously, the jaundice had been more or less constant but of a moderate degree. While she had been up and about most of the time, her strength and weight did not return to normal. She had a great deal of itching of her skin. She still had much indigestion from fatty foods.

Physical examination showed a woman forty-four years of age, with a moderate jaundice. There were many scratch marks over her skin from the itching. She was somewhat obese, being 67 inches tall and weighing 154 pounds. Her normal weight was 170 pounds. General examination was negative except for a high right rectus incisional scar, through the central portion of which oozed clear bile.

Laboratory studies indicated a mild secondary anemia (hemoglobin 72 per cent) and an obstructive type of jaundice (serum bilirubin 18.0). Other laboratory findings were irrelevant.

After proper rehabilitation with transfusions, administration of vitamin K, liver, iron, et cetera, exploration of the abdomen was done on December 24, 1946. The previous scar was removed, and after considerable dissection of many fibrous adhesions, the biliary fistula was followed to its origin. The liver appeared normal. During the course of the dissection, the gall bladder was found but was necrotic and wrapped in omentum. A small perforation in the fundus of the gall bladder connected to an adjacent portion of the lesser curve of the distal part of the stomach, allowing a small amount of bile to gain entrance to the intestinal tract. An attempt was made to identify the cystic duct but this, along with the entire visible portion of the common duct, was obliterated. The biliary fistula was then seen to arise from the cut ends of the two hepatic ducts. After these were clearly defined, a vitallium tube, Y-shaped, was used to reconstruct and make possible the continuity of the biliary tract. One arm of the tube was placed in the hepatic ducts and the vertical section in the divided distal end of the common duct. The remainder of the gall bladder was then removed.

Convalescence was essentially normal. The jaundice rapidly cleared up, there was no drainage from the wound, and the urine and stools soon became normal. She left the hospital on the twelfth postoperative day. Advice was given her as to biliary flushes as described, and she has now remained completely symptom free for two years and two months after the operation. There has not so far been any evidence of attacks of cholangitis or hepatitis.

Summary

1. The causes and prevention of benign strictures of the biliary tract, exclusive of congenital lesions, have been discussed, along with a few words about the general disease picture and its care.

2. Too great emphasis cannot be made of the fact that the great majority of these lesions are man-made, and therefore preventable.

3. Some of the more recent concepts in the surgical correction of these conditions have been presented.

4. A case report is given in which reconstruction of the biliary tract was carried out using a vitallium tube, resulting in a successful outcome of an individual whose common duct had been severed twenty months previously during cholecystectomy.

COLLES FRACTURES AND THEIR TREATMENT IN GENERAL PRACTICE

ROGER G. HASSETT, M.D.
Mankato, Minnesota

COLLES fractures, next to fractures of the ribs and fingers, have been stated to be the most frequent of all fractures and, because of this frequency, have for the most part fallen into the hands of the family physician for treatment. It is common, particularly in country practice, to see a great variety of deformed and chronically painful wrists. This is unquestionably due in a great part to the fact that the physician has been too easily satisfied with a reduction which is inadequate or that proper x-ray diagnosis, both preoperatively and postoperatively, has not been obtained. The greater percentage of these fractures are associated with marked edema and swelling, which necessitates careful diagnosis and handling. In other instances where the deformity is not too evident and is masked by slight swelling, a bandage or cast has been applied without any attempt at reduction. It is good practice to consider all injured wrists as fractured until definitely proven otherwise. This is especially true in patients over the age of forty.

Proper x-ray diagnosis should include four views: anteroposterior, posterior-anterior, lateral and oblique. Often the slight compression with resultant deformity and disabling weakness is missed in the conventional anteroposterior and lateral x-ray views. In addition to these factors, slight fractures of the carpal bones are more readily visualized. Pentothal sodium has afforded us with a safe, simple and quick method of anesthesia, and no attempt at reduction should be made without this aid because of the extreme pain associated with these injuries. I have stayed away from local infiltration of novocaine because of the possibility of introduction of infection and because of its inability to completely relax the pull of the muscles of the forearm.

In a discussion of Colles fractures we are only concerned with extension and compression fractures of the lower end of the radius, except in instances where the styloid process of the ulna may be involved. The term, Colles fracture, is too loosely used by the medical profession. The condition originally described by Colles was a transverse fracture 4 cm. above the joint line with displacement upward and backward of the lower fragment. This site is, however, rare, for these fractures for the most part occur one-half to three-quarters of an inch above the articular margin and are usually associated with some degree of comminution of the lower fragment. The transition of the dense cortex of the shaft into the cancellous lower portion is the point of least resistence and the usual site of fracture.

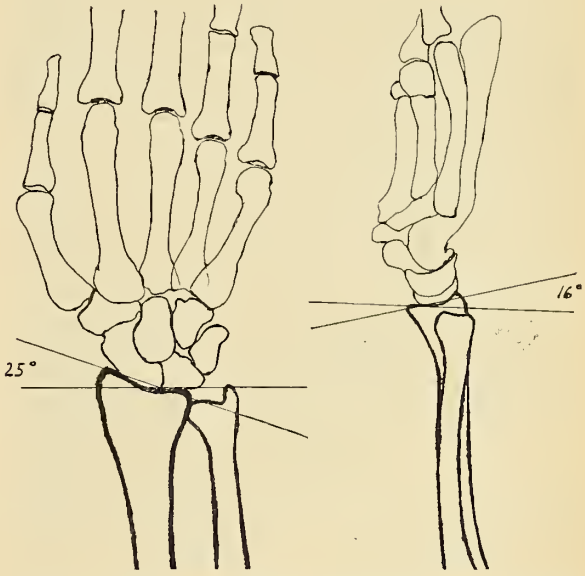

Fig. 1. Diagram taken from x-ray of normal wrist joint in the (a) posterior-anterior and (b) lateral positions, showing the articulations and angles which should be present in the well-reduced Colles fracture.

The incidence of Colles fracture is most common in early youth, in the farming industry and in the "falling down" aged. In early youth, due to the fact that the lower end of the radius develops from a single center which appears at the end of the second year and forms an epiphysis which unites with the shaft at the age of eighteen or nineteen, the epiphyseal injury or separation responds readily to simple leverage reduction. In the aged and in industrial injuries with marked fracture deformities the problem of proper reduction is not so simple.

The wrist joint has been described as consisting of three joints, the radiocarpal, the intercarpal and the carpometacarpal joints. The radiocarpal joint with which we are concerned in this discussion

Read at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1948.

is the articulation between the scaphoid and semilunar bones and the lower articulating surface of the radius. The articulating surface of the radius is concave and directed downward, forward and inward. The joint cavity is convex both in its upward and lateral diameters. Knowledge of the normal joint angles as seen on x-ray are important to proper anatomical reduction. I wish to repeat that in the normal anteroposterior view the articular surface of the radius is inward, forward and downward, and, with the arm held upright, forms an angle of approximately 25 degrees from a horizontal line through the joint (Fig. 1a). In the lateral view likewise the articular surface facing downward forms an angle of 16 to 20 degrees toward the flexor surface of the forearm (Fig. 1b). Good reduction must nearly as possible conform to these angles. Grossly, then, the reduced fracture will show the hand at mid-position in an ulnar deviation of about 25 degrees.

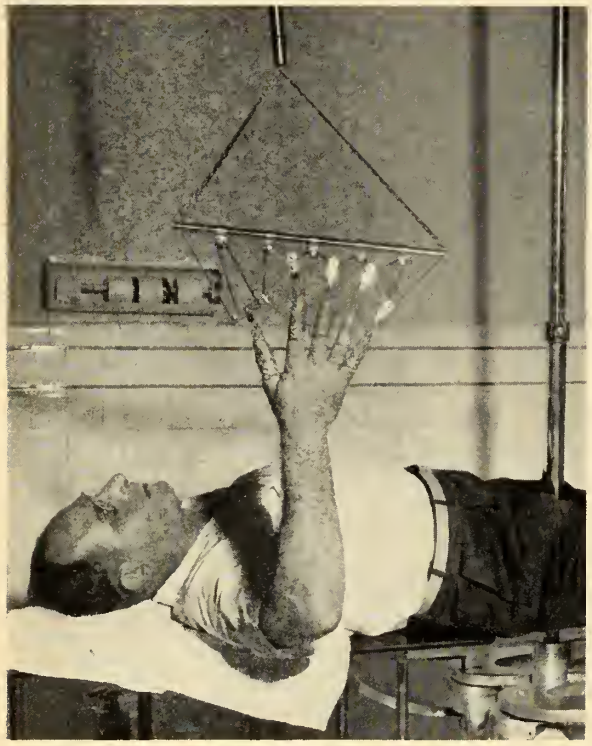

Fig. 2. Application of the suspended finger trap with the arm and forearm "hanging out" and the patient under complete anesthesia. The hand is in mid-position with correct ulnar deviation. Fluoroscopic examination is easily facilitated, and casting or other fixation is completed before releasing the finger traps.

For the purpose of treatment, Colles fractures should be classified as:

1. Incomplete fractures of the lower end of the radius.
2. Complete fractures of the lower end of the radius.
3. Fracture of the posterior articular margin.
4. Oblique fractures of the styloid process of the radius.
5. Complete fractures of the lower end of the radius with displacement.

The first four groups are amendable to simple treatment by fixation with the various splints and casts with the hand and forearm in the mid-position. The fifth group comprises the great majority of all treated wrist fractures and practically always involves some degree of impaction or entanglement of fragments which, if not reduced, results in permanent deformities. This type as well has the marked early swelling due to severe trauma of the soft parts which lends an additional problem in diagnosis and reduction. Early replacement of the lower end of radius in its approximately normal position is necessary if one is to expect a functional wrist. I wish to emphasize the need for early reduction which tends to minimize the eventual swelling.

There are two methods of reduction: reduction by leverage and reduction by traction and molding. Leverage in the hands of the skilled operator is very successful, but likewise in the hands of the ordinary operator has been in a great part the cause of insufficient and poor reduction. Undoubtedly this is due to the inability to break up impactions and fragment entanglements.

With the usual traction method a pad is placed over the flexor surface of the upper arm proximal to the elbow and a band or strap fixed to the floor or operating table or held by an assistant for counter-traction. The operator grasps the hand, exerting traction and combined hyperextension to break up the impaction. Molding is accomplished with the palm of the other hand of the operator. Considerable assistance is needed to maintain a reduction until fixation is accomplished, usually by direct skin casting.

For the past three years, I have employed the use of a finger trap (Fig. 2) in all instances of forearm and wrist fractures. This particular trap (Siebrandt) engages all four fingers and the thumb. The wire spring traps are attached by adjustable cords and pulleys to a metal bar, which

in turn is attached above to a 30-pound calibrated spring cylinder by a metal chain. After applying the traps, the entire apparatus is suspended through a pulley from the ceiling of the operating room or from an overhead metal bar attached to the fracture table. With the arm suspended at a 90 degree angle, and the patient in the supine position, counter-traction is applied as usual by a band across the flexor surface of the upper arm proximal to the elbow (Fig. 3). A 15-pound pull is exerted for fifteen minutes, after which the fracture site is examined by portable fluoroscope or x-ray. In most instances, the fracture will be found completely reduced. Molding or further manipulation, if necessary, is easily done without any assistance. This method employs the use of fluoroscope or x-ray to verify the reduction before permanent fixation is applied. It is surprising how little traction force is necessary to reduce moderate displacements sufficiently. In a great number of instances, by just "hanging the arm out" in the trap without any counter-traction except the weight of the arm, complete reduction will be accomplished under general anesthesia, which aids relaxation of muscular spasm.

The criteria for complete reduction are:

1. Ability to completely flex the wrist as compared with other normal wrist.
2. The radial styloid is one finger's breadth below the styloid prominence of the ulna.
3. The normal convex contour of the dorsal surface of the lower radius has been restored and the radial adduction deformity has disappeared.

In the very severe fractures with marked comminution and radial shortening, there actually is complete bone destruction. In order to arrive at a final functional wrist, continuous traction and counter-traction must be maintained until new callus and bone fragments have been consolidated to give normal bone length. Skeletal pinning and external fixation, as described by Anderson and O'Neil of Seattle, Washington, in a paper written and published in *Surgery, Gynecology and Obstetrics* in April, 1944, has given us the best answer to this too frequent crippling problem. For traction, a Kirchner wire or small Anderson pin is passed through and through the distal one-third of the second metacarpal or the center of the first metacarpal. This pin or wire is connected to a "U" bar carrying an Anderson double clamp. Counter-traction is accomplished by two half pins inserted at opposite angles into the lateral aspect of the radius above the fracture site. After

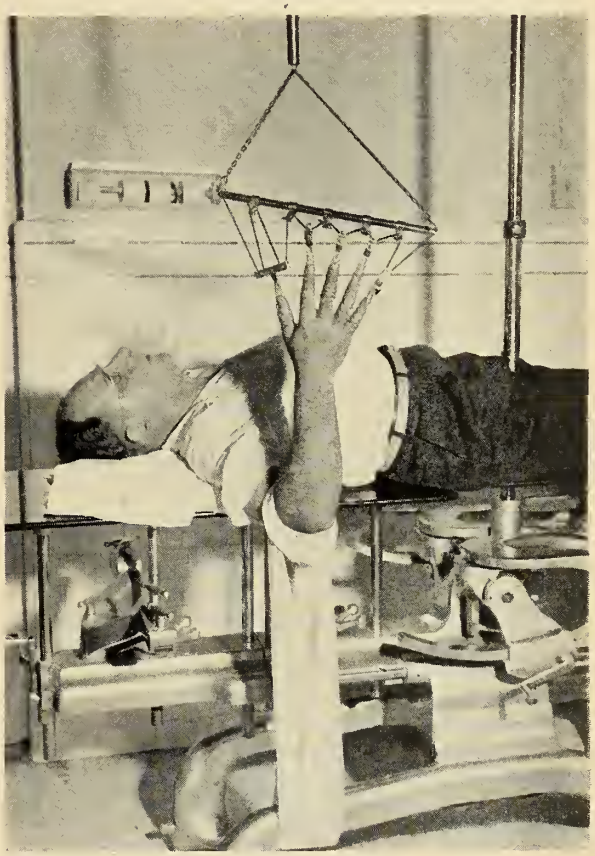

Fig. 3. Reduction of fracture impactions and comminutions with the application of 15-30 pounds of counter-traction as measured on the scale suspended from the overhead table bar.

manual reduction and radial length have been accomplished with the finger trap, two fixation rods are applied between the one half-pin unit in the upper radius and the "U" bar attachment in the second metacarpal bone. This method facilitates early function of the entire hand and even permits considerable pronation and supination of the forearm. Activity of the hand is encouraged immediately, and the use of a sling or other support is discouraged. Eight to twelve weeks are necessary in this apparatus for sufficient consolidation to be accomplished. This period of time can be determined only by x-ray. A number of my colleagues feel that skeletal pinning and external fixation should not be confined to the severe comminuted type of fracture. Too often, after adequate reduction and casting and with the

OVARIAN PREGNANCY

W. J. DEWEESE, M.D.
Bemidji, Minnesota

THIS report was inspired by a patient with an ovarian pregnancy upon whom it was our privilege to operate, and is presented to add this one case to the accumulated literature regarding this rare and interesting condition.

Ovarian pregnancy is the rarest of the primary forms of gestation, except for the cervical, which is almost unique,[1] and for the abdominal. DeLee[9] quotes Werth as considering primary abdominal pregnancy so rare that it need not be considered, but Curtis[5] states that several authentic cases of primary abdominal pregnancy have been recorded.

The possibility of ovarian pregnancy was first suggested by Mercer in 1614,[22] but it was not until 1682 that Maurice claimed the first reported case.[16] Following this, numerous cases were reported, but analysis of these disclosed them to be inconclusive for the most part. Catherine van Tussenbrock in 1899 is credited with the first complete histological description of an ovarian pregnancy, and Thompson in 1902 was the first American to demonstrate an undeniably authentic specimen.[22,24,25]

The literature following this becomes very confusing as to the actual number of genuine cases of ovarian pregnancy. Norris listed nineteen positive cases up to 1909, and Geller finds a total of forty-five cases up to December, 1941.[11] Novak, in his textbook published in 1940, wrote that there were about fifty reported cases in which the diagnosis of ovarian pregnancy is based on acceptable evidence.[18] Smiley, in October, 1944, states that only about fifty cases in the literature can fulfill rigid requirements,[19] while Stamm in June, 1946, reports eighty-five proven cases.[2] The last article to appear on the subject, by Wittenberg in April, 1948, presents a case which the author considers to be the eighty-first.[25]

The actual incidence of ovarian pregnancy would be probably much higher if all hemorrhagic lesions of the ovary were subjected to pathologic study. The incidence has been estimated at one in 25,000 pregnancies, and to be from 0.7 to 1.07 per cent of all ectopic pregnancies.[3,14]

Ovarian pregnancy has been classified into two main types, the primary and the secondary. The primary implies that the ovum is fertilized while it is still within the graafian follicle, and there implants and grows. This was considered by DeLee[9] and others to be the only type, but now a second type, the secondary or superficial, is considered, wherein the ovum is fertilized after its release from the follicle and subsequently implants itself on the surface of the ovary.

The rarity of ovarian pregnancy, inasmuch as the ovary and the ruptured follicle are so accessible to the sperm cells, has been explained by the fact that the ovum as it exits from the ovary must undergo maturation before it is capable of being fertilized. This normally occurs during its passage into and through the outer portion of the tube.[25]

It is conceivable that the ovum, after having been fertilized as usual in the fallopian tube, might travel in a retrograde manner and lodge in the still gaping follicle, there to develop and be classified as a primary ovarian pregnancy.[4,19] Or a tubal pregnancy may abort, and, if the separation of the placenta has been rapid and the chorion is in good condition, it may implant on the ovary, or elsewhere, and continue to grow.[21]

Endometriosis has been noted on several occasions to be associated with ovarian pregnancy, and it may be that ovarian implantation cannot take place in the absence of endometrial tissue on the ovary.[19] The fact that the ovary is the most frequent site of endometrial implants bears some support to this, but many cases have been described with no signs whatever of endometriosis. Decidua itself is not necessary for the implantation or continuation of a pregnancy.[14]

The implantation on the ovary is pathologic from the beginning, and is doomed to failure sooner or later. The ovary reacts with the formation of a pseudo-decidua consisting of fibrin, lutein cells, and masses of trophoblasts.[11] The early implantation and placentation do not differ greatly from intra-uterine pregnancy except for the absence of true decidua.[25]

The usual course of ovarian pregnancy is rupture of the ovary and extrusion of the products of gestation into the abdomen within the first trimester.[9,20,25] Following this, molar formation, including hydatidiform, has, on occasion, been observed.[9] But, surprisingly enough, some are car-

Read at the annual meeting of the Northern Minnesota Medical Association, Duluth, Minnesota, August 20, 1948.

ried long enough to produce a viable baby. In a survey of the literature, Nicholls finds that thirty-eight cases of ovarian pregnancy have gone to the age of viability of the fetus (seven months), from which were salvaged twelve living babies and twenty-two living mothers. He adds a case of his own where both the 10 pound 3 ounce child and the mother lived.[17] Of those reaching full term, the usual termination has been death of the fetus following an unproductive period of labor.[20]

The symptoms of ovarian pregnancy resemble very closely those of tubal ectopic pregnancy, from which it cannot be differentiated except at laparotomy. It may rupture later than the usual tubal pregnancy, and there may be less uterine bleeding. The pelvic pain may be less acute since there are slight, if any, muscle cramps.[19]

The differential diagnosis of ovarian pregnancy is the same as for the more common tubal ectopic pregnancy.

From the pathological standpoint, the criteria of diagnosis of ovarian pregnancy were formulated by Spiegelberg in 1878, and are quoted by Dale as follows:[6]

1. The tube, including the fimbriated end, must be intact and must be distinctly separate from the ovary.
2. The gestational sac must definitely occupy the normal position of the ovary.
3. The gestational sac must be connected with the uterus by the utero-ovarian ligament.
4. Unquestionable ovarian tissue must be demonstrable in the walls of the sac.

DeLee, however, states that to establish the anatomic certainty of an ovarian pregnancy, all that is necessary is to prove that "the tube, including the fimbria ovarica (excluding also gestation in an accessory tube), is absolutely free from any part in the formation of the fetal sac."

The treatment of ovarian gestation is that of any ectopic pregnancy: excision of the products of gestation as soon as the diagnosis is made, and the patient's condition permits.

Case Report

Mrs. E. D., a twenty-four-year-old white woman, was referred to us by Dr. Harry Palmer of Blackduck, Minnesota, and was admitted to the Lutheran Hospital at 12:30 a. m., January 9, 1948, with the chief complaints of severe lower abdominal pains and vaginal bleeding.

The patient stated that her last menstrual period had begun on November 17, 1947, and was a normal period of five days' duration. Her menses had previously been regular, occurring every twenty-eight days. Since her last period, she had noted some enlargement of the breasts, but had experienced no nausea.

On December 22, 1947, five weeks after her last menstrual period, she had suffered an attack of severe lower abdominal pains, crampy and intermittent in nature, that

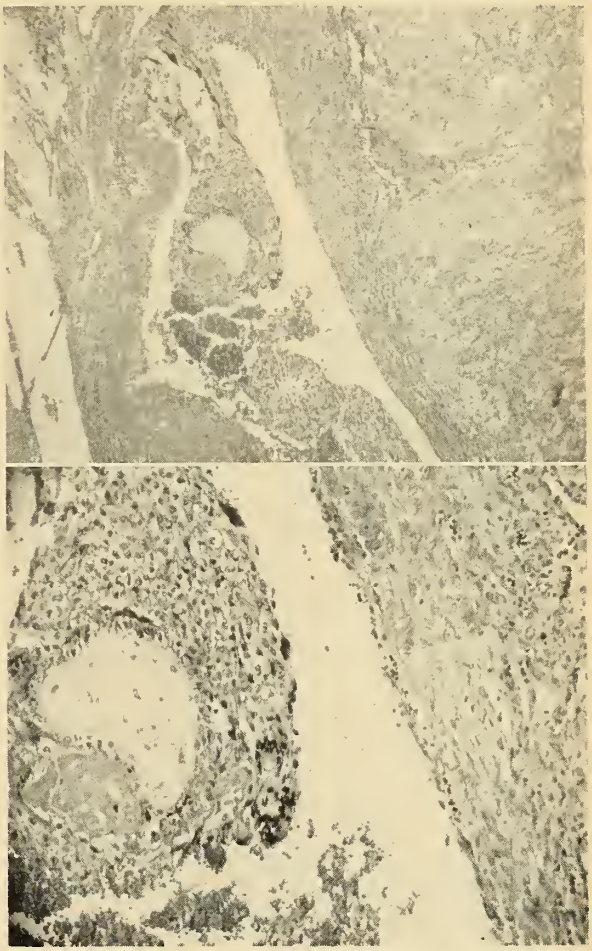

Fig. 1. *(above)* Photomicrograph of a section of the right ovary, showing corpus luteum on the right and a cross-section of placental villus just to the left of center.

Fig. 2. *(below)* Higher power view of same section, with corpus luteum on the right and placental villus, surrounded by decidua-like cells, on the left.

were described as going through to her rectum. There was no nausea, vomiting, bowel upset, or collapse. These pains lasted about two days. On December 27, 1947, she began to have moderate and irregular vaginal bleeding, which continued up to the time of the hospital admission. At 4:00 p. m. of the day before admission, she had again experienced sudden and severe pain in both lower quadrants of the abdomen, associated with weakness. She had not fainted. She was seen by her home physician and sent to the hospital with the diagnosis of a ruptured ectopic pregnancy.

The past history revealed only that she had a son four years old, with no other pregnancies, and that she had been slowly losing weight for the past three years.

The significant findings of the physical examination

were as follows: temperature 97°F.; pulse 68, regular, fair quality; respiration 18; blood pressure 92/50. She was a thin but well-developed white woman, very pale. Her skin was warm and dry. Breasts showed increased glandular tissue, with no secretion or masses. There was fullness of the lower abdomen; muscle guard in the right lower quadrant with severe rebound pain; very tender throughout the lower abdomen, more on the right, with doughy resistance to pressure. There was decreased resonance on percussion over the suprapubic area, extending into the right flank; very few peristaltic sounds were heard. Liver dullness was present; the liver, spleen and kidneys were not felt. Pelvic examination showed no active bleeding. The cervix was soft, with marked pain on any motion of the cervix. A soft fullness was felt in the cul-de-sac and on the right side; the uterus could not be outlined because of abdominal muscle guard. Pelvi-rectal examination showed a soft bulging fullness in the cul-de-sac, more on the right; no definite mass was felt.

The white blood count on admission was 22,450. The red blood count was 3,610,000 with a hemoglobin of 70 per cent. The urine showed a trace of albumin, with 8 to 10 white blood cells and 6 to 8 red cells per high power field. The diagnosis of a ruptured right tubal pregnancy was made. Donors were obtained, and the patient was given two 500 c.c. transfusions of whole citrated blood.

At ten-thirty a. m. on the day of admission, the patient was operated upon under ether anesthesia. On opening the abdomen through a suprapubic midline incision, a large amount of liquid and clotted blood was encountered and evacuated. The cul-de-sac was filled with clotted blood. The uterus was enlarged to one and one-half times the normal size and was soft, but otherwise normal. Both tubes and the left ovary were entirely normal. The right ovary was 3 cm. by 6 cm. in size, and had an undisturbed anatomical relationship with the broad ligament and the uterus. The fimbriated end of the right tube was entirely free from the ovary. A cyst 2 cm. in diameter filled with partly clotted blood was seen in the right ovary. There was placental tissue firmly adherent to, and growing from, the free border of the right ovary. Several pieces of placenta, undergoing necrosis, were found lying free in the cul-de-sac. The fetus, which should have been 15 mm. in length, was not found. The appendix, cecum and pelvic colon were normal. No endometrial implants were seen. After the pathological condition was identified, the right ovary was delivered, the mesovarium and the ovarian ligament clamped across, and the ovary removed. Two suture ligatures were used to close the mesovarium. The fluid and clotted blood and the loose placental fragments were removed from the cul-de-sac and the abdomen was closed in layers with silk. The appendix was not removed. Five hundred c.c. of whole citrated blood was given during the operation. The postoperative course was uneventful. The red cell count was 4,610,000 the afternoon of the operation, with a hemoglobin of 93 per cent.

The patient was allowed to walk the day following operation, and was discharged from the hospital on the third postoperative day, to be ambulatory at home. She returned to the office for the removal of skin sutures on the seventh postoperative day, at which time the wound was well healed. The patient has since become pregnant again.

Pathological study of the specimen was performed by Dr. Kano Ikeda of Saint Paul, Minnesota, whose report is as follows:

"Gross: The specimen consists of an ovary, slightly enlarged. It contains a large corpus luteum, about 2 by 1 by 1 cm. Alongside of it is a hemorrhagic area about 2 by 2 by 1.5 cm. which apparently has ruptured into the abdominal cavity, from which are obtained several clots of blood.

"Microscopic: The ovary is diffusely edematous and shows several cystic follicles. There is a large, well-developed corpus luteum with hemorrhagic center. Alongside of the corpus luteum, and tightly adherent to it, is placental tissue showing signs of hemorrhage, infiltration of chorionic cells in the wall, and numerous well-developed chorionic villi.

"Diagnosis: Ovarian ectopic pregnancy."

Summary

A case, proven by operation, is presented which satisfies Spiegelberg's four criteria for a true ovarian pregnancy.

GLOMUS TUMORS

J. GRAFTON LOVE, M.D.
Rochester, Minnesota

GLOMUS tumors produce severer and more disabling pain than any tumor known to the oncologist. When fully grown these tumors are, however, the smallest (Fig. 1) of any of the tumors usually presented for treatment; that is, at the time a glomus tumor is removed it is smaller than any other tumor that the surgeon encounters. This tumor apparently occurs infrequently, yet once the condition is known and understood and the method used to make a diognosis is appreciated, many more of these tumors than are anticipated may come to light and consequently many more patients than heretofore will be relieved of distressing pain which often has been attributed to a functional disturbance.

In 1935 I[3] reported the first case of glomus tumor that I had seen and called the attention of the members of the clinic staff to this unusual and very interesting neoplasm. Since that time I have seen, diagnosed and surgically removed fourteen glomus tumors. Other surgeons at the Mayo Clinic also have removed glomus tumors and in our experience the results have been most gratifying.

The patient who has a glomus tumor frequently is middle-aged or older. The chief complaint is severe pain which usually centers around a small area on one of the extremities. The pain may be localized sharply or, what is more frequently true, the pain may extend up or down the extremity from the site of the lesion. Often the lesion seems entirely too small to produce the amount of pain of which the patient complains and obviously suffers. When an attempt is made to palpate the lesion, the patient will withdraw the extremity for fear that excruciating pain will be produced.

The normal glomus from which these tumors arise is located most commonly in the subungual region and a frequent site for a glomus tumor is underneath a fingernail. Nevertheless the tumor may be deeply situated. In the case of a patient who was seen recently (Case 2) the tumor was situated along the periosteum which covered the posterior aspect of the femur. The true subcutaneous glomus tumor also may not be visible, but if the region of the tumor is stroked or touched the patient will exclaim, due to the severe pain which is caused.

The first point in the diagnosis of this lesion is to suspect it. When a patient complains of an excruciating, lightning-like pain for which there is

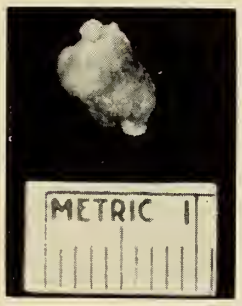

Fig. 1. A subungual glomus tumor. This tumor was larger than most glomus tumors of the subungual variety.

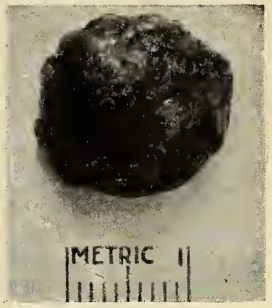

Fig. 2. Extremely large glomus tumor which was situated deep in the popliteal fossa (Case 2).

no obvious cause, a careful search should be made for a glomus tumor. The one special test which I have found to be of most value in the location and subsequent diagnosis of the lesion is the one which I have called the "pin test."[4] This test is employed as follows.

An ordinary steel pin is used. The patient is asked to indicate the point of maximal pain or tenderness. Often, as the physician passes his finger toward the spot of maximal pain, the patient will withdraw the extremity, just as the patient with trigeminal neuralgia will withdraw his face when the trigger zones[2] are approached. However, when the patient's confidence is gained, the point of a steel pin can be pressed into the skin as near as 1 cm. to the lesion without producing severe pain. As soon as the point is pressed over the lesion, the patient will have an attack of excruciating pain. On many occasions when I could not see the lesion, I have been able to identify its location and make the diagnosis with the help of the pin.

Tumors which might be confused with glomus tumors are the neurofibromas, angiomas and melanoepitheliomas. A plantar neuroma,[1] which today is recognized as the cause of so-called metatarsalgia, is another tumor which might also be

From the Section on Neurologic Surgery, Mayo Clinic, Rochester, Minnesota.
Read at the meeting of the Southern Minnesota Medical Society in Winona, Minnesota, September 13, 1948.

confused with the glomus tumor. As a rule, neurofibromas are much larger than glomus tumors before they produce symptoms comparable to those of glomus tumors. An angioma, on palpation, would not produce the pain which is so characteristic of the glomus tumor although it may look entirely like a glomus tumor. A melanoepithelioma might resemble a glomus tumor superficially but again it does not produce the pain which is characteristic of a glomus tumor.

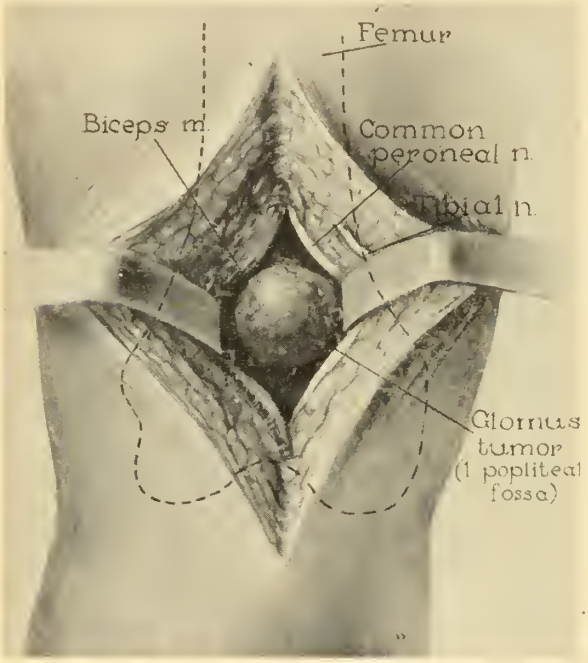

Fig. 3. Relationship of the tumor to popliteal fossa (Case 2).

The treatment of the glomus tumor is excision. Roentgen therapy and radium therapy have not proved of value. The lesion should be recognized as being benign, and unnecessary amputation of a finger or an extremity should not be carried out. The excised tumor should be submitted to a competent pathologist who is acquainted with glomus tumors; he will identify the microscopic characteristics by which the tumor may be recognized.

Since these tumors are unusually small and consist of blood vessels as well as muscle and nerve fibers, the lesion may be difficult to find at the time of exploration. I prefer not to put the patient to sleep until the site of the lesion is identified or very closely approximated or until the tumor is exposed surgically. My practice is to identify the site of the lesion with a wheal needle on a Lundy syringe containing 0.5 per cent procaine hydrochloride. After the site of the lesion is identified, field block is carried out proximally in order to block off the area of the tumor so that the tumor may be exposed while the patient is awake. As the tumor is approached the severe pain becomes greatly exaggerated. It is important not to inject any solution into or immediately adjacent to the tumor, for to do so may result in blanching the tumor and consequently it will be difficult to distinguish it from the adjacent tissues.

As a matter of fact, it often has been necessary for me to have the patient undergo general anesthesia as the tumor itself is approached. Particularly is this true if the tumor is deeply situated, as for instance, in the calf or the thigh. The subungual variety of lesion and that which is located superficially in the skin and could not be easily lost, can be removed completely with local infiltration; general anesthesia in such cases is not necessary. The following reports of cases are illustrative of glomus tumor, the difficulties which may be encountered in its diagnosis and the gratifying result which may be obtained when the tumor is recognized and successfully removed.

Report of Cases

Case 1.—A woman, fifty-one years of age, had noted a small red spot beneath the nail of the third finger of the right hand for sixteen years. On the slightest touch she experienced pain. Gradually the pain became paroxysmal and continued to increase in frequency and intensity. The pain extended from the finger to the hand, forearm, and shoulder. During the two years previous to her registration at the clinic she had had severe pain in the right upper extremity without any stimulus, such as touching the finger. The "tumor" as she described it had become larger and the nail had become slightly raised. The pain had become unbearable and she was anxious to obtain relief. Examination of the finger disclosed a slightly elevated fingernail and a small tumor beneath. The findings were typical of a glomus tumor; diagnosis was made and surgical removal of the tumor was advised and accepted. Local anesthesia was used. The distal three-fourths of the nail and nail bed were removed and a small tumor was exposed. The tumor, although it was compressed, had elevated the nail and it rested on the dorsal aspect of the ungual phalanx of the ring finger of the right hand. The entire tumor was removed along with some of the tissue about it. Then the portion of the ungual phalanx which had been depressed by the tumor was curetted and a vaseline gauze dressing was applied. The tumor measured only 1 mm. in diameter and the findings, on microscopic examination, were typical of a glomus tumor; namely, vascular elements, muscular elements and nonmedullated nerve fibers.

Case 2.—The largest glomus tumor which I have re-

moved had afflicted a woman twenty-six years of age. This woman's chief complaint was weakness and pain in the left leg of thirteen years' duration. Exercise caused increased pain and she could not run or dance. At the age of twenty years the pain began to involve most of her left leg. It finally became so severe that it was difficult for her to get around. At the time this patient came to the clinic she had pain constantly. She said the pain was aggravated by cold damp weather. Heat did not give complete relief. During the four years previous to the patient's registration the left leg had felt weaker and it became increasingly difficult for her to walk. When she did walk, she had a distinct limp on the left side.

Examination revealed exquisite tenderness in the left popliteal fossa and detailed palpation was impossible. The circumference of the left leg was 1.5 inches (3.81 cm.) smaller than the right and that of the left thigh was 2 inches (5.08 cm.) smaller than the right. Results of a neurologic examination were entirely negative. There was no evidence of vascular disease; that is, all arterial pulsations were normal. There was no evidence of arterial insufficiency. She did have some secondary vasomotor spasm which, in the opinion of the consultant, probably contributed to the coldness of the leg, but not to the pain. A tentative diagnosis of glomus tumor in the popliteal fossa was made and exploration of the tender area was advised and carried out. Under local infiltration with 0.5 per cent benzoyl-γ-(2-methylpiperidino)-propyl hydrochloride (metycaine) at the site of maximal tenderness, the exploration was started. When the common peroneal nerve was exposed the patient had considerable pain but when the nerve was retracted, the maximal tenderness was found to be much deeper. The pain was so great that it was necessary to anesthetize the patient with pentothal sodium given intravenously. The dissection was then carried down to the level of the lower end of the femur just above the knee joint and a bluish tumor mass was encountered in the loose areolar tissue adjacent, but not attached, to the joint and not attached to the periosteum of the femur. The tumor was typical of a glomus tumor, in every way except for its extreme size (Fig. 2). After adequate exposure of the mass, it was freed and removed in its entirety. The wound was closed in layers without drainage. Figure 3 shows the relationship of the tumor to the surrounding structures. When the patient awoke from the anesthesia she was free of pain and has remained free since.

Summary and Conclusions

Glomus tumors are small, benign neoplasms which arise from the normal structures found in the body, namely, cutaneous neuromyoarterial glomera. The tumors are usually subcutaneous and characteristically subungual in location. However, they may be deeply situated as in the case reported in which the tumor rested on the lower end of the shaft of the femur. Severe pain is the chief complaint. When the tumor is suspected a diagnosis can usually be made. The treatment is complete excision of the tumor. The removal of such a tumor usually results in cure. At the Mayo Clinic we have not had any experience with recurrence, although recurrences have been reported in the literature. The tumor is benign and amputation of a digit or extremity probably is not justifiable.

Case Report

WATERHOUSE-FRIDERICHSEN SYNDROME

DAVID A. SHER, M.D.
Virginia, Minnesota

THIS is a case report of an eight-month-old male infant that was referred by Dr. Snyker of Ely, Minnesota.

The infant was admitted to the Virginia Municipal Hospital on June 11, 1948, at 6:45 p.m., and expired about forty minutes later. The complaints, as given by the mother, were as follows: About five hours previous to admission, the infant became suddenly ill with a fever of 105.6°, followed shortly by a bluish discoloration of the lips and nails. Soon after, the infant developed pin point reddish areas, followed by enlarged spots of reddish color all over the body. About 5:00 p.m., the infant became stuporous. He was seen by the private physician, who advised hospitalization in Virginia. The mother stated that the youngster had had whooping cough six weeks previously, but for the past two weeks there had been no cough and no signs of any disease. On the morning of admission, the youngster awoke perfectly well, ate a usual breakfast and noon meal, and appeared to be in good health until the sudden onset of high fever at about 2:00 p.m. The family history was irrevalent. There were two siblings, living and well; both had had chicken pox and pertussis the past spring. The father and mother were living and well.

Examination.—The baby was well developed and well nourished. He was in a state of stupor and appeared moribund; the lips and nails were cyanotic; the skin was mottled, and the child was covered from head to foot with purpuric spots, varying in size from 1 mm. to 2 cm. The pupils were dilated and fixed, and did not react to light. The optic nerve was hemorrhagic on opthalmoscopic examination. The fontenel was soft. There was no nuchal rigidity. The arms and legs were flaccid. The Babinski reflexes were positive. The head and upper part of the body were very hot; the legs and lower abdomen were very cold. The abdomen was rigid. There were no evident jerking movements of the body or extremities. The ears, nose, and throat were negative. The baby was typed for transfusion, given coramine, vitamin K, and oxygen; and while the transfusion was about to be started, the infant expired. An attempt by the laboratory technician to get sufficient blood for blood study was unsuccessful. However, sufficient blood was obtained for a blood smear. The smear revealed 99 per cent polymorphonuclear cells and 1 per cent lymphocytes.

The autopsy findings, as reported by Dr. George Berdez, pathologist, were as follows: A well-nourished male infant measuring 28.5 inches and weighing about 22 pounds. Numerous erythematous patches and hemorrhages of the skin measuring up to 2 cm. in diameter. These changes were most marked on the chest and abdomen. The arms, legs, face, and mucous membranes also displayed hemorrhagic areas. On opening the abdominal cavity, the abdominal viscera was found to be within normal limits. The adrenals were very large, about three times the size of normal. On cut surface both adrenals showed a large hemorrhage in the medullary substance, and the cortical layers were also infiltrated with diffuse hemorrhages. The kidneys were normal. The patches of Peyer of the small intestine and the solitary follicles of the large intestine were prominent. The left lung showed small hemorrhages of the visceral pleura; the tissue, congested and infiltrated with hemorrhages, showed areas of beginning bronchopneumonia. The right lung showed a similar condition.

Diagnosis.—(1) Massive bilateral adrenal hemorrhage—consistent with the Waterhouse-Friderichsen syndrome. (2) Beginning bronchopneumonia. (3) Erythematous hemorrhagic eruption of the skin.

I believe this case fits into the entity known as the Waterhouse-Friderichsen syndrome, and would like to briefly summarize this condition.

Discussion

The Waterhouse-Friderichsen syndrome is a clinical pathological entity that is receiving more widespread recognition in diagnostic circles. Although much discussion has arisen as to the proper application of this term, present opinion would reserve its use for those cases in which there is a fairly constant group of clinical signs and symptoms typical of a fulminating septicemia: sudden onset, hyperpyrexia, purpura, cyanosis and shock, associated with a definite pathological picture embodying adrenal hemorrhage.

History.—The earliest report[4] of this condition appeared in 1894 when Valcker described fulminating purpura with bilateral adrenal hemorrhage. In 1911 Waterhouse[8] presented a similar series of cases with which he associated a distinct clinical picture. Friderichsen[1] in 1918 summarized the literature, but it was not until 1933 that the designation of Waterhouse-Friderichsen was attached to the disease by Glanzmann[2]. In a recent summary of 125 cases,[3] twenty-nine had been reported since 1941.

Etiology.—Various organisms were postulated as the etiological agent. However, careful bacteriologic studies in more recent times have shown the condition to be almost exclusively the result of fulminating menginococcemia. Thus, Thomas[6] reported a series of twenty-six patients dying as a result of menginococcemia before typical meningitis symptoms occurred. Of twenty-three autopsies in this series, seventeen had bilateral adrenal hemorrhage. No restricting age incidence was reported, although the majority of cases occur in children, ninety per cent in those nine years and under.

Symptoms and Course.—The patient is typically described as being in perfect health until the onset. In classical cases, the child awakens from sleep with a cry. He may be seen within two or three hours by a physician, during which time the hyperpyrexia, marked malaise, headache, vomiting, and abdominal pain usually

Presented before the Northern Minnesota Medical Society, Duluth, Minnesota, August 21, 1948.

is present. The first characteristic feature which usually prompts hospitalization is the accompanying cyanosis of the lips and nails; closely following this the purpura manifestations occur. These show themselves as hemorrhagic areas, usually beginning on the limbs, trunk, and mucous membranes as tiny isolated points which rapidly enlarge and coalesce. The petechiae have dark red or purple centers which do not fade on pressure. They develop very rapidly, literally under the observing eye. Hyperpyrexia is universally present. Various investigators report a notable fall in blood pressure readings. This is a direct indication of the tremendous circulatory collapse accompanying the toxemia. The typical picture is that of a fast, weak, irregular pulse; shallow respirations; pallor; slowing of the heart rate, and a terminal fall in blood pressure and temperature, followed by death in four or five hours after the onset. Associated features occurring as part of the picture of shock are Cheyne-Stokes respirations, urinary incontinence, coma, and delirium. Fleeting signs of pulmonary involvement are often seen. Occasionally neurological signs such as muscle flaccidity, tremor, chills, convulsions, and rigidity of abdominal muscles are observed.

Until recently very few reports of recovery have been brought forth. Several instances of recovery from what apparently appeared to be a fulminating meningococcemia have been reported, but whether the adrenals were involved cannot be ascertained. Most of the cases are fatal. It has been suggested that those individuals who have recovered from fulminating meningococcemia be followed for the possible development of Addison's disease.[7]

Treatment.—1. Combatting bacteremia: sodium sulfadiazine intravenously and subcutaneously, maintaining a blood level of 15 mg.[7] Penicillin is of questionable value but should be tried.

2. Overcoming circulatory collapse: adrenal cortical extract and adrenalin. Transfusion and vitamin K.

3. Supportive measures: (1) fluids and plasma; (2) respiratory stimulants, coramine, and oxygen; (3) sedation for delirium; (4) nasal suction for abdominal distension, if present; (5) saline enemas. The treatment, to be effective, must be started early.

Laboratory Findings.—Recovery of organisms from (1) spinal fluid, (2) blood culture, (3) petechial hemorrhagic areas. Spinal fluid and blood findings are inconsistent. Bleeding time and clotting time are normal.

Pathological Features.—1. Predominant pathological feature is that of hemorrhage into the adrenal gland. Bilateral hemorrhage occurs in 95 per cent of the cases.[8] At autopsy, the adrenals are enlarged, dark red and bluish purple in color, and contain massive intercapillary hemorrhage.

2. Extensive purpuric eruption is found on the face, extremities, and buttocks.

3. A fairly constant finding is generalized hypertrophy of the lymphatic tissue. Signs of meningeal irritation are notably absent.

Summary

1. An increasing number of cases of the Waterhouse-Friderichsen syndrome have been reported in recent years, probably due both to its more accurate recognition and to the increased incidence of meningococcic infections during the past few years.

2. The condition is believed to be the result of fulminating meningococcemia and shock, and the pathologic findings can be explained by the toxic results of the organism.

3. Present usage of the term, Waterhouse-Friderichsen syndrome, should be confined to those cases exhibiting the fairly typical clinical course as described, and undoubtedly to those patients whose symptoms are confirmed by autopsy.

4. The present outline of treatment centers on control of the bacteremia, on measures aimed to combat shock and secondary symptoms, and on supportive treatment.

COLLES FRACTURES AND THEIR TREATMENT IN GENERAL PRACTICE

(Continued from Page 271)

recession of edema and swelling, "slipping" occurs within the first two weeks and, if not recognized by x-ray, ultimate deformities result. With pinning and fixation checked by x-ray, this occurrence is impossible, and an earlier functional wrist and hand is obtained. The technique of pinning is easily acquired and should readily be accomplished by the good general practitioner.

In conclusion, the use of a finger trap has greatly aided me in arriving at uniformly good reductions in all Colles fractures, and skeletal pinning and external fixation have aided in the moderately severe displacements and have given me a method for continuous traction and counter-traction in the severe comminuted fractures which have always produced permanent crippling. Frequent x-ray examination will verify this reduction especially during the first two weeks.

History of Medicine In Minnesota

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

(Continued from February issue.)

Dr. William S. Wood was born at Hornicorn, Wisconsin, August 1, 1873. His father, William C. Wood, was born at Frost Village, Province of Quebec, Canada; and his mother, Fanny (Seelye) Wood, was born at Queensburry, New York, June 29, 1847. Both his parents died at Faribault, Minnesota, in 1921. Two surviving members of the family are a sister, Mrs. Florence S. Gardner, who now resides at Faribault, and a brother, Dr. Harry C. Wood, a long-time member of the Mayo Clinic staff, Rochester, Minnesota.

Dr. William S., before entering college, was a student at Shattuck School in Faribault. He graduated from the McGill University Medical School in 1896, and was a member of the Zeta Xi Fraternity. He practiced his profession at Geneva, Freeborn County, for a few years, paying particular attention to eye, ear, nose, and throat. From Geneva he moved to Blooming Prairie, Minnesota, and practiced there until he went abroad for further study. He spent two years, 1905-1906, in Europe touring the continent but especially studying in Vienna, where he specialized in eye, ear, nose, and throat. Upon his return he practiced his specialty at Albert Lea, Owatonna, Faribault, and surrounding towns. He had not located permanently when he was stricken with tuberculosis and went to Arizona. He returned to Faribault and died there March 16, 1910. Dr. Wood was a member of the Episcopal church. He never married.

Dr. H. G. Lowithean, a graduate of Hamline Medical College, 1894, located at Glenville in January, 1895. He married Miss Jennie E. Lewis of Glenville in 1895. In June, 1896, he sold his drug store and located at Fairmont. In 1900, according to the records of the State Board of Medical Examiners, he was located at Dennison, in Goodhue County.

Dr. Gilbert G. Belsheim was born on a farm near Forest City, Iowa, August 31, 1871. His father, Guldbrand G., and mother, Guro (Sather) Belsheim, immigrated to America from Norway in pioneer days. He was raised on a farm, attended rural schools and later the Forest City, Iowa, High School. While at Forest City he was domiciled in the home of Dr. Harry Irish, a man of noble character and a splendid physician and gentleman, and became interested in medicine. He attended the University of Iowa Medical School and graduated there in March, 1895.

After graduation, he practiced a few months at Kensett, Iowa. In 1896 he located at Albert Lea and practiced there until 1900, part of this time serving as health officer. In 1900 he moved to Northwood, Iowa, where he practiced until 1903. In the fall of that year he entered Luther Theological Seminary, Saint Paul, as a student of theology and was ordained into the ministry in 1906.

Three brothers, Ole G., a clergyman; Gullik, an attorney; Andrew G., a doctor;

and two sisters, Anna and Dena, comprised the family. Dr. Belsheim was twice married. His first wife, Emma Caroline Isaacson of Thompson, Iowa, bore him one son, George N., now a teacher of music in Minneapolis public schools. His second wife, Grace Christensen, bore him two children: Margaret and Harold, the latter a theological graduate who served as chaplain in the U. S. Army European Sector, during World War II. Dr. Belsheim died at Fort Dodge, Iowa, in May 1930, aged fifty-eight.

Dr. Gustav W. T. Barck was born at Barkaynd, Sweden, May 10, 1832. His genealogy dates back to one Hans Barck, a German baron who emigrated to Sweden in 1670 and settled at Stromstad, where he became a merchant. His father, Rev. Gustaf O. Barck, son of Regimental Commissary Hans Lorentz Barck, was born at Lille Holma, February 5, 1804. He was ordained at Wesjo, March 10, 1837, "after foreign examinations had indicated him to have a well-grounded insight." He served pastorates, founded his own private schools, and was famous as a teacher of Latin. In a résumé of his activities dated July 19, 1872, he speaks of his own private school "honored by the confidence of parents of many different communities." He cites the example of one "Robert Henning Edward Hedenstierna, enrolled by me at age seven years, who could, at ten years of age, let the incumbent Bishop, Esias Tegner, Dean C. L. Henlin, and Professor J. L. Wickelgren, on one and the same day, hear one of his age speak Latin with unusual ease." His father married Ulricka Fredricka Lundquist on March 6, 1832. In the résumé dated July 19, 1872, he speaks of his children as follows:

"None living in Sweden. Of the sons, Gustaf Wilhelm Theophil and Axel Edwin Theodore, will here only say that they, more than twenty years ago, journeyed to the United States of North America, after being duly accredited and provided with passports, the former a doctor and owning his own pharmacy, and the latter a teacher of song and music, who also conducts a considerable business in music and musical instruments. So far as is known they honor the Swedish name, have a good livelihood, and enjoy respect. They appear for the present not to wish to re-visit Sweden. *Habiant sibi!*"

From the above information it may be assumed that Dr. Barck had a well-rounded preliminary education in his father's private school and that he, too, at the age of seven years was reading Latin.

The following is quoted from direct information presented by his son, H. A. Barck, of Albert Lea:

"Dr. Gustaf W. Barck, son of a minister, and rector of the parishes of Qvenneberga and Hjoresberga, being the eldest, was supposed, according to custom, to follow in his father's vocation, a minister of the Gospel. But he seemed to have an unconquerable desire to study medicine. This was so apparent that evidently his father gave up all his fond hopes in this matter. Then his mother came to his rescue and plans were made and perfected for sending him to Heidelberg, Germany, for his education in medicine. I remember father's telling us about his stay at Heidelberg. He said the first year was mostly a round of singing, drinking, and dueling, but after that it was downright work and study.

"After his degree in medicine was conferred, he immediately directed his course to that 'land of lands,' America. He arrived in New York City with only three dollars in his pocket but was most fortunate in obtaining a position in a hospital to tide him over, for a time, with food and shelter included. Throughout his stay in New York he continued to yearn to see America. After accumulating sufficient funds he proceeded west as far as Denver, Colorado. There he joined a group of gold prospectors who were bound for South America. He mentioned one experience in which, snowbound in the southern Rockies, with food unobtainable, they resorted to digging out hibernating rattle snakes, which when properly prepared were found to be palatable and adequate for such an occasion.

"Finally, the trip reached a point near the border of South America, from which they

began their return. As they journeyed north, rumors of war between the states was heard; and on entering, they found it already in progress. It soon dawned on my father that the group he was traveling with was all on the side of the Confederate Army. This did not appeal to him, and when they arrived at a Confederate enlistment barracks, he decided to seek the Union Army, in which he enlisted as a surgeon and served in that capacity. After his discharge from service he practiced for a time at Galesburg, Illinois, and from there came to Freeborn County, locating at Freeborn and later at Albert Lea. He married Miss Amelia A. Dunn of Freeborn on May 15, 1867. Seven children were born to them, of whom two now survive: a daughter, Mrs. Florence Crowley, Glendale, California; and a son, Horace A. Barck of Albert Lea. Dr. Barck died at Albert Lea, March 27, 1913. His wife died at Freeborn, May 6, 1894."

From a letter written to his fiancee, dated Aug. 1, 1862, the following is quoted:

"You are probably somewhat astounded to hear of me in Virginia; but such is nevertheless the case. I am here serving my (our) country in capacity of surgeon in Capt. Phillips' Battery E., Reg. Light Artillery, Ill. Volunteers. Our present camp is one-half mile west of Martinsburg. I write these lines under a large oak tree, and in every direction I see the footprints of war. We are only five miles from the enemy's pickets. A few days ago, a charming lady, a secessionist, spat on an officer of the Twelfth Illinois Cavalry. The provost marshall ordered two men with an American flag to take the lady to headquarters. They did so, and when there she was asked to beg the officer's pardon. She refused and the Colonel then ordered her to be wrapped up in the flag and sent to jail. You should have heard her scream then, 'Take that accursed thing off me! that flag of pirates, of d—m Yankees,' and such. It quite maddened me to hear the thing talk, and I never felt more like dispatching a mortal to the care of 'Charon' than then."

It is difficult to correlate the activities of Dr. Barck. Exact year of emigration to America, how long he practiced in New York, when and how long his ventures were into the West and to South America, how long he practiced in Galesburg, Illinois, and the exact date of location at Freeborn are not known. From his letter to his fiancee, August, 1862, it seems evident that he was at Freeborn sometime prior to that date. We do know that he was a well-educated, well-qualified physician and surgeon, a gallant gentleman, gracious and willing in his service to his pioneer friends and patients, and that he died at age eighty-one with the honor and profound respect of a thankful community.

HISTORY OF MEDICINE IN LE SUEUR COUNTY

Under "Minnesota" the *Encyclopedia Britannica* makes the following statement: "A little north of the center, the state is traversed from North-West to South-East by the extensive forest known as the 'Big Woods'." At the time when the first doctors came into the territory, five-sixths of Le Sueur County lay in this Big Woods area, leaving only the Le Sueur and Ottawa prairies clear. In contrast to Le Sueur County, the County of Nicollet, across the Minnesota river, was primarily prairie land with few obstacles between the doctor and his patient.

Conditions were far from easy for pioneer doctors in Le Sueur County. There an early practitioner was often forced to set out on horseback with a load of bulky medicines in his saddle bags and wend his way slowly—never more than two or three miles an hour—along narrow trails through nearly solid woods. After several hours he would eventually arrive at some distant, one-room log house, warmed by a fireplace and lighted by a wick wound around a stick projecting from a holder

Most of the material in this report is provided by a writer who wishes to remain anonymous. Additional notes have been furnished by Dr. H. B. Aitkens of Le Center, Minnesota.

containing grease. These conditions prevailed until, in the process of time, roads were built and wheeled vehicles could be used. But even then the mode of travl was determined by the conditions to be found on the most difficult part of each particular journey.

Medical service to the early inhabitants of the Minnesota valley and surrounding territory was conditioned by three factors: first, the terrain and the climate; second, the settlers themselves, their impermanency and financial condition; and, third, the stage of development medicine had reached. Of these, the latter was the most important.

In 1850 medical science was an infant in the cradle. There was a small body of scientific fact which was presented in lectures to medical students, but there were no such diagnostic procedures as blood counts or test meals, and the chemical analysis of urine had barely started. The clinical thermometer was not in use, although it had been invented; and the stethoscope was still new and crude. A microscope had not yet been brought to this country from England, and when it did make its appearance, there was normally about one for every 100 medical students.

When an advance was made in medicine it was likely to remain local for some time, in contrast to the present day when the news of medical discoveries is flashed around the world almost immediately. When Semmelweiss in 1847 made his notable advance in midwifery, his discovery hardly spread outside of the hospitals in Hungary where he practiced. It was not until after 1883 that Lister first heard of Semmelweiss. Lister's own great contribution, his work on antisepsis, began in 1864; his first publication on it was made in 1867. Scotland, his native country, was slow to take up Listerism and was preceded in its adoption by Germany, which held great festivals in Lister's honor in Munich and Leipsig in 1875 and by France. In America, a rising young surgeon, W. W. Mayo, was first to adopt Lister's method of antisepsis in 1883.

"Fever", "liver complaint", "lung disease", "inflammation", "kidney trouble"—those were common diagnoses. Anatomy at this time was indeed objectively being taught by dissection of the body, but without investigation into the cause of death. Any bedside instruction was postgraduate, from a preceptor. Chloroform was a few years old, fortunately. The knife was not yet widely used as a therapeutic instrument. Face to face with an illness, the doctor had to proceed empirically to do his best, using means that had seemed to be of benefit in what appeared to be a similar case. An old-timer said of an early doctor that "he was a good nurse"; and perhaps, unwittingly, that was a compliment. Doctors were not, as a matter of fact, highly esteemed; they were, in many cases, called only as a last resort—partly, perhaps, on account of expense.

The absence of legal requirements and the remoteness from medical education facilities combined to work additional disadvantages to the early practitioners and the pioneer residents. It was not until 1883 that adequate legislation regulating the practice of medicine was passed by the state legislature. A previous attempt in 1869 to write a law protecting the people of Minnesota from charlatans and quacks was a failure and was repealed. Vital medical training was virtually unattainable; at least it was not to be had without the expenditure of great sums of money for expensive medical courses in the East.

Since there were no railroads, the population centers in the Minnesota Valley were on one side or the other of the river, which served as the main thoroughfare. In 1860, the total number of persons living in Le Sueur county was a little more than 5,000, and at that time, just as for the next fifteen years or so, the tendency for the inhabitants to settle along the river made it possible for physicians to reach a large part of their scattered patients by crossing in the ferry or in a canoe.

Physicians in one county often attended patients in the other county, that is, when the condition of the river permitted. At times when the river was impassable, as it was at certain seasons, medical needs in Nicollet were looked after entirely by St. Peter physicians and Le Sueur County by Le Sueur physicians.

Obstacles such as storms and blizzards, deep snow and impassable trails could be overcome by determined men. The big blizzard of 1873, credited with taking at least forty lives in Minnesota and Dakota and causing hundreds of cases of frozen limbs, as recalled by Dr. Asa W. Daniels, pioneer practitioner in Nicollet County who died in 1923, provides a typical picture of what a blizzard could mean to an early doctor. According to Dr. Daniels, the morning of the blizzard was warm; the snow was melting and there was a heavy fog. In the forenoon, he had visited Cleveland, Le Sueur County, and at two in the afternoon he proceeded to New Sweden, fifteen miles away. Arriving at his destination, the farm home of a Mr. Peterson, Dr. Daniels merely blanketed his horses instead of putting them in the barn because the day was so warm. He had not been at the Peterson home for more than twenty minutes when a roar of wind shook the house, alarming the whole household. The doctor immediately started out for his home in St. Peter with the wind at his back; but the storm became more and more severe until the horses were a mere blur in the driving snow and road dirt. He was almost to the village when he was forced to let the horses go. Fortunately, after struggling through countless drifts, he stumbled upon a fence which he was able to follow to a farm house. There he found that the farmer was still in town and that he and the farmer's wife would be obliged to saw wood to keep from freezing. He slept in the attic with only his fur coat for a cover and with the snow drifting in through the many cracks. For three days he did the chores until the farmer could return.

A Le Sueur County doctor had a similar experience. The husband of a sick woman came into the village to summon him. The doctor went immediately to his patient while the husband was delayed in town, getting supplies. A severe storm arose so that the husband was unable to return home; and for three days the doctor had to keep the farm stoves going by working with the bucksaw and had to care for the farm animals and do the other chores.

Dr. H. B. Aitkins of Le Center recalls having to attend an obstetrical case five miles outside of town during a snowstorm. The farmer called for him with a team and bobsled, but on the way the sled had to be abandoned, and the doctor, with his heavy obstetrical satchel, and the farmer continued on horseback until one horse was exhausted and the trip had to be completed with only the remaining horse. The birth was delayed and, since he was afraid that if he left the house he would be unable to return, the doctor remained at the farm during the entire blizzard.

The poverty of the early settlers was for the most part extreme; hence payment to physicians was very uncertain. Government terms for homesteading were occasionally changed, and at one time a jest was current to the effect that the government was willing to bet 160 acres of land against a small payment that one could not live on the land for five years without starving to death. Most settlers eked out a living clearing forest land, for which wealthy persons would pay six dollars an acre; making maple syrup, selling muskrat or mink hides, catching fish, killing prairie chickens, and gathering ginseng. This latter activity of digging the ginseng root and selling it to dealers proved very profitable for some. The root—which actually had no pharmaceutical or therapeutic value—because of its resemblance to the body of man, that is, in the form of a fork, with an occasional intermediate rootlet, led the Chinese to attribute to it the power of restoring virility to the aged and impotent. It was because of this belief that many an early physician was indebted to the Chinese, who paid cash for the root of ginseng and thus kept early

physicians' families from starving. It has been recorded that at one time the village of Henderson had one doctor, one baker and *seven* ginseng dealers.

Dr. Otis Ayer had the distinction of being the pioneer physician in Le Sueur County. About 1856 he arrived in the village of Le Sueur, the first settlement in the county, situated on the Minnesota river. During the New Ulm massacre* Dr. Ayer was one of the physicians who cared for the many wounded. He was a graduate of Dartmouth and Jefferson Medical college. A physician of the old school, he was dignified, able and devoted to his work. These qualities made him one of the outstanding physicians of this part of the country. Dr. Ayer practiced in Le Sueur village until his death.

Four miles west of the village Dr. W. W. Mayo, father of Drs. W. J. and C. H. Mayo, settled, shortly after Dr. Ayer. In 1859 he moved into the village and built a comfortable house, according to pioneer standards. Two years later he went to New Ulm as a surgeon for the United States Army, and early in 1863 he moved to Rochester where he founded the famous clinic.

Another early resident was Dr. Andrew J. Rutan, who represented the county in the first state legislature (1857-1858). At the time he was living in Lexington township, but in 1862 he moved to Le Sueur and practiced medicine in the village for about a year. There is no record of any other physician making his home in Le Sueur County during the fifties.

Dr. A. C. Smith practiced in the town of Le Sueur during the early sixties. A newspaper note gives us the information that the doctor helped to bury the Indians killed at Scotch Lake in 1862. Some years later he moved to Cleveland. In 1863 J. L. Whipple opened an office in Cleveland. After the war S. B. Umphrey came to Cordova. He practiced in the county for many years. In 1865 the first drug store was opened by H. H. Mackstroth, who also practiced medicine to a limited extent during the sixties. Other newcomers about this time were F. Vasterling (who died at the age of ninety in 1905), A. F. Randall, H. Davis, J. Horst and W. H. Woods. In 1869 James Holmes, a graduate of Jefferson Medical college, and S. M. Morrison, one of the many "botanic" physicians then popular, came to Le Sueur.

It is probable that the county officials began to appoint physicians to care for the poor early in this decade. The first record we have is the appointment of S. B. Umphrey.

In November, 1869, Dr. Umphrey, together with Drs. A. F. Elliott, R. Randall and H. Davis, gathered at Cordova to form a county medical society in order to meet the requirements of an act passed by the state legislature "to protect the people of Minnesota from empiricism and imposition in the practice of medicine and surgery."† The law was a much needed one in the state, since the more isolated the practitioner and the greater the difficulties of practice, the greater was the need for good preliminary preparation. At the same time, as noted previously, there was less likelihood that these requirements could be met, for during the sixties and seventies, medical and surgical education at all worthy of the name was to be obtained only by attending Eastern medical schools, which cost a great deal in time and money.

The state law requiring that a man have either a diploma from a medical school or a certificate from a medical society in order to practice medicine in the state was repealed the year following its approval, and it was not until 1883 that an adequate measure was passed by the state legislature. The provisions of the Act of 1869 did not apply to anyone who had been in practice for five years prior to its passage. The

*See Medical History of Brown County.

†Chapter 41, Laws of 1869, approved March 9, 1869, and repealed February 24, 1870.

county medical society, formed in compliance with the state law, is peculiar in that it constituted itself a local examining board for physicians. Lack of further mention of the society in the local newspapers leads one to believe that its life was a short one.

The articles of incorporation of this Medical and Surgical Society of the County of Le Sueur are here given:

I

Place of Location: Cordova.

II

Purpose: The advancement and improvement of the members thereof in the sciences of medicine and surgery, and in the practice thereof, and the various subjects appertaining or germane thereto, and by mutual examination and interchange of opinion and experience among the members thereof touching the said sciences and the practice thereof, at stated or other meetings of the members of the corporation; and to instruct and examine persons pursuing the study of the said sciences of medicine and surgery, and the granting of certificates of qualification to practice medicine and surgery or either of them to persons of good moral character, who shall upon full examination be deemed qualified to practice the same according to the provisions of the act entitled *An Act to Protect the People of Minnesota from Empiricism and Imposition in the Practice of Medicine and Surgery,* approved March 9, 1869.

III

Any person, possessing the qualifications prescribed by the said act to practice medicine or surgery or any person of good moral character who is pursuing the study of medicine and surgery or either of them with intent to qualify himself for the practice thereof and to engage therein, may become a member of this corporation by signing the articles and paying the sum of five dollars.

IV

Examinations of persons applying for certificates of qualification to practice medicine and surgery or either of them, shall be made at a stated or special meeting of the members of said corporation, and shall be conducted in such manner as the members present direct. When so granted, such certificate shall be signed by the president or vice president, attested by the secretary and sealed with the corporate seal of this society.

V

The officers of the corporation are: A. F. Elliott, president; R. Randall, vice president; S. B. Umphrey, secretary; H. Davis, treasurer.

Dated: 20th of November, 1869.

Recorded: 24th of November, 1869, 4 P.M.

(1870-1879)

Among the physicians who practiced in Le Sueur County for short periods during the first years of the seventies were M. W. Scott, Guy Daly and D. B. Collins. Isaac Cosner and C. Hoberg of Nicollet County often extended their practices into Le Sueur County. C. J. Spratt, a graduate of Bellevue hospital and college, came to Le Sueur in 1870 and left in 1883. George D. Swaine also practiced there for about ten years (1872-1882). E. P. Case, a prominent physician in the county and an early member of the state medical association, opened an office in Waterville. Among those who came a few years later were T. W. Hammond, H. C. Leonard; J. A. Scammon, J. S. Seely, J. W. Dal, W. G. Goffe (1881-1884) and Lambert Laurens. Few of these men remained permanently. In the fall of 1879 the town of Le Sueur had a total of six resident physicians.

Throughout these years there were occasional deaths from typhoid fever. In Ottawa there were several mild cases of smallpox in 1870. Two years later Mackstroth and Sons' Drug Store was advertising smallpox vaccine, apparently as a result of a number of cases of smallpox in neighboring counties.

Although the local papers seem not to have mentioned it, we learn from St. Peter, across the river, that scarlet fever was raging in Le Sueur in the spring of 1877,

and that a number of cases had proved fatal about twenty-four hours after attack. In 1878 an epidemic of mumps struck the children of Lexington township, and a few months later there was a general epidemic of cholera morbus. Diphtheria prevailed in Cleveland and Ottawa in 1879.

Dr. Otis Ayer, who regularly attended meetings of the Minnesota State Medical Association since its founding, served as its president in 1878. Dr. E. P. Case, another local physician, became a member at that time.

Among those who served as county coroner were Charles J. Spratt (1872), S. B. Umphrey (1873, 1877, 1878) and J. S. Seely (1879). By the end of the period the office of county physician was awarded to lowest bidders in each of the five commissioners' districts. Salaries usually ranged from about fifty to eighty dollars. Sometimes physicians were not paid regular salaries but were paid for each separate call. In 1879, for example, E. P. Case agreed to act as county physician at fifty cents a visit and thirty-five cents a mile, one way, and to furnish medicines himself. Occasionally other physicians also turned in bills for work done for the poor.

During the later years of the period there appeared from time to time in the newspapers articles concerning public health. Dr. H. C. Leonard, for instance, had an article on diphtheria in which he quoted Dr. Charles Hewitt, secretary of the Minnesota State Board of Health, urging people to use stone or brick curbing rather than wood so as to assure safer drinking water. Another of Dr. Leonard's articles, entitled *Homeopathy versus Alleopathy,* endeavored by means of very queer statistics to prove that the death rate for the most common diseases was 100 per cent using the latter treatment and far less under the former.

An ever-increasing number of physicians came to Le Sueur County during the eighties, and the short periods of time that many of them stayed give evidence that the population was not sufficiently large to support them all. Collections were bad, owing to the poverty and transiency of many of the inhabitants. In many instances remuneration for services came in the form of farm products. One of the druggists in the western part of the county said that for seven years his prescription files averaged one prescription in seven days and that drugs were generally bought in five-cent lots.

There was probably an average of twenty to twenty-five practitioners in the county in any given year during the period. At one time (1884), there were ten physicians in the town of Le Sueur. Among the newcomers in the early days of the decade were W. W. Clark, William Dodge, H. Mager, J. A. Reynolds, H. E. Lucas, C. P. Dolan, William Netter, and J. G. Bemis. W. H. Fisher, a homeopath and his wife, Ann, practiced in Le Sueur for a number of years. Franklin A. Dodge, a graduate of the University of New York City, opened an office in 1886 and became one of the prominent physicians in this part of the state.

(To be continued in the April issue.)

President's Letter

RURAL HEALTH — WHOSE PROBLEM?

Too often we, as a nation and as individuals, are more concerned about our illnesses than our health.

The sharpest application of this truism is, perhaps, found in the rural areas of the United States where medical care is admittedly uneven in distribution and where preventive medicine and safety programs have to combat staggering odds to chalk up semi-satisfactory records.

Who's to blame for the delayed progress of rural health? The farmers? In part. The doctors? To a degree. The medical schools? They too must share the responsibility, as must all of the organizations designed for and including rural people.

Certain it is that the Washington planners who would force our free economy into the straitjacket of socialism are looking hopefully at rural health statistics for justification of such drastic action. For example, posing as a textbook, a volume called *Rural Health and Medical Care* has recently come off the presses. Depression-year statistics and typical "Americans can't afford health" propaganda have been blended together with the help of such medical-muddlers as Drs. Isidore S. Falk and Michael M. Davis and, from the Social Security Administration, Margaret Klem.

This is typical of what we observe constantly and may continue to expect from the Ewing coterie. After painting the rural health picture in blacks and greys, they attempt to show how "free medical care" would brighten the rural environment.

Scientific medicine, public health workers, farm groups do not claim such a guaranteed cure-all. Experience and observation have proved that there is no one answer to the rural health question, just as there is no one cure for cancer. But the answers will be found in both cases by the scientifically tested method of pooling the results of experimentation and continuing to build on a proved foundation.

How this theory works is evidenced by the rural health conferences sponsored annually by the American Medical Association's Committee on Rural Health. More than 600 leaders of all groups and organizations which interest themselves in bettering rural health met February 4 and 5 at the Palmer House, Chicago, and discussed every phase of farm welfare, from increasing soil fertility to securing more doctors for rural areas.

It was generally agreed that the voluntary way is the desirable way and plans were considered for extending Blue Cross and Blue Shield coverage and assisting other forms of medical insurance. Inducing doctors to choose rural practices, too, was deemed a joint responsibility; medical schools must encourage rural migration; farm communities must aid in obtaining the facilities for practice and in making the rural environment satisfactory for the doctor and his family. Safety and preventive health programs will continue as focal points in the objectives of many organizations.

By working together, erasing duplication and going toward preconceived goals, we will solve the rural health problem; we will have a complete cure, not just the temporary absence of symptoms under socialistic anesthesia.

THE BIRTH OF MEDICAL FREEDOM

THE publicity campaign that the medical profession is initiating to bring to the people of the United States the advantages of private practice over government-supplied medical care, so that they through their representatives in Congress may chose intelligently, may well determine the most momentous political issue of our generation. The question resolves itself into essentially a choice between compulsory government insurance, with the government providing all medical care through taxation, and voluntary health insurance, with the maintenance of the American system of free enterprise. Government medicine is socialism, whereas voluntary health insurance preserves the freedom of the individual. The socialization of medicine has been the initial step in other countries sought by the socialists in the establishment of a completely socialistic government. For this reason, the medical profession is spearheading a fight against socialism and should have, and doubtless will have, the support not only of allied groups such as the dentists, druggists, hospitals and pharmaceutical houses, but of all private industry. The socialists in our government and labor unions are obviously adopting the war slogan of divide and conquer. If the citizens of our country who believe in free enterprise wish to prevent the ultimate complete socialization of our economy, it behooves them to join the medical profession in opposition to this movement.

The enormous growth of hospital and medical insurance in our country the past few years indicates the belief on the part of our citizens that insurance is a means of meeting the cost of sickness. There is little indication of any great demand on the part of the people for the government to take over their medical care. The demand comes from a comparatively small group of government officials in Washington and a few labor union officials who are socialists. The various Wagner-Murray-Dingell bills have been written by employes of various government bureaus in Washington. The very preamble of the recently submitted bill is misleading by inference when it states that this national health program is necessary to promote personal relationships between physicians and patients; to promote more effective co-ordination among general practitioners, specialists, nurses and hospitals; to enable patients to have more effective free choice in selecting their physicians; to provide adequate health services consistent with the highest standards of quality, to be administered locally in accordance with American ideals of democracy and individual freedom. The medical profession maintains that the proposed bill would do just the opposite of all this.

Already there is evidence that the proponents of the bill are not hesitating to smear the medical profession. Oscar Ewing, Chief of Social Security, has already accused the medical profession of selfishness in opposing the bill and of raising money for the most powerful lobby in Congress—both misstatements. He insists on distorting the statistics as to rejections in the draft to indicate the inadequacy of medical care under our present system.

The fight is on. We, as a profession, are fighting for our independence. It is worth while fighting for and is worth much more than the twenty-five dollars we have assessed ourselves. Those who do not think this freedom is worth the price, let them stay out. There may be some question as to the constitutionality of an assessment of this amount. Let those who want to haggle over the point do so, but let those who want to preserve the institution of private practice send their checks, made out to the American Medical Association, to our State Association office.

The preliminary announcements of the methods of publicity to be used in our National Education Campaign are impressive. Emphasis is to be placed on educating the people. The contact of doctors with their patients is to be stressed, and leaflets will be supplied for inclusion with monthly statements. Similar material will be furnished for allied professions and industries. Business and civic associations, farm, fraternal, religious and veterans organizations will be asked to help.

The question has been raised by some newspa-

pers as to whether they can expect paid advertisements. Those in charge of the campaign have decided it is inadvisable to undertake any broad advertising campaign in the newspapers or over the radio ostensibly against a piece of legislation. When it is realized that a quarter page advertisement in each of the 12,000 daily and weekly newspapers in the country would cost a half million dollars, the futility of such a program becomes apparent. It would likewise be a mistake to patronize a selected few newspapers. Publicity material, however, will be mailed to the newspapers, many of which consider our cause their cause.

If the profession fights to a man and each does his part, with the help of those who cherish their freedom from bureaucratic control, the battle will be won.

OLMSTED-HOUSTON-FILLMORE-DODGE SUPPORTS AMA SOCIALIZED MEDICINE FIGHT

FIRST official county response to the American Medical Association's assessment request has come from the Olmsted-Houston-Fillmore-Dodge County Medical Society. Checks totaling almost $14,000 have been relayed to the state office.

Ninety-eight and seven-tenths per cent of the staff of the Mayo Clinic and Foundation have given their support to the American Medical Association's educational campaign to defeat compulsory health insurance. Additional staff members, now ill or absent from Rochester, will, it is anticipated, make a comparable response to the AMA's appeal.

It is stimulating, indeed, to observe this demonstration of medical society unity, particularly in view of recent newspaper reports which insinuated that discord was arising on the question of participation in AMA plans.

"The members of the staff and the fellows of this institution are well aware of the efforts of the American Medical association to devise methods for distributing medical care more widely by means of voluntary prepayment plans," stated Arlie R. Barnes, chairman of the Clinic's Board of Governors, and Victor Johnson, director of the Foundation, "and, almost unanimously, they desire to support these efforts.

"It is to be hoped that such methods for extending medical care as might be devised by the American Medical Association will safeguard or even improve the present high quality of medical service, and that the program will be such as to enlist the continued wholehearted support of virtually all the physicians of the country. It is highly desirable that physicians present a united front in efforts to improve the distribution of medical care."

Earlier publicity on what an official of the local medical society refers to as "the sincere remarks of a small minority," engendered some misunderstanding about the position of the Clinic and Foundation staff on the AMA anti-socialized medicine program. Prompt response to the AMA assessment request has established, beyond doubt, Mayo physicians' belief in the methods to be employed by the American Medical Association in maintaining freedom of medicine.

G.A.E.

NARCOTIC PRESCRIPTIONS

THIS ISSUE contains an article by Mr. A. M. Bangs, District Supervisor of the Bureau of Narcotics in Minneapolis, on the subject of telephoned narcotic orders. The filling of narcotic prescriptions has been a thorn in the flesh for physicians and druggists alike ever since the present regulations were established. There need be no difficulty when the physician telephones a prescription from a residence and leaves a prescription there to be picked up by the druggist on delivery. If, however, he neglects to leave the prescription, the druggist is not allowed to leave the medicine, and trouble ensues. Also, if a physician, receiving a telephone call from a patient requesting a prescription, calls the druggist and promises to send him the prescription and then fails to do so, there is trouble. If the need is urgent, the druggist is allowed some leeway in sending the drug before he receives the prescription but he must have the prescription for his files. So it behooves the physician to carry out his part in providing the prescription and not to vent his ire on the druggist who did not make the law but is periodically checked to see that he is obeying it.

The federal law applies only to narcotics and not to the barbiturates. Our state law is more stringent than the federal. The only narcotic allowed by the state without a prescription is cough mixture containing 1 grain or less of codein to the ounce. Prescriptions must be used for the barbiturates but orders for refills may be given over the telephone.

As long as there are individuals who lack self-control when it comes to the use of narcotics and barbiturates, laws to control consumption will be

necessary, not only for the welfare of the individual but for society at large. Although regulations seem rigid and bothersome, they have proved necessary in the control of these drugs, as most physicians know.

DIPHTHERIA

IN 1948 there were only 129 clinical cases of diphtheria reported in the state, with seventeen deaths. This is the lowest record in history. This does not mean, however, that the profession should feel complacent over the progress made. Diphtheria is one of the few diseases which can be completely controlled, and there should be no relaxation on the part of the profession or the public in the immunization program.

As a result of the comparative rareness of the disease today, many recent graduates have never seen a patient with clinical diphtheria. Diphtheria, in spite of its rarity, should always be borne in mind when the patient complains of a sore throat. The presence of a dirty gray membrane which, though characteristic, is not always present, should result in the taking of cultures; and if the lesion strongly resembles diphtheria, antitoxin should be given at once instead of waiting for the report from the culture.

The incidence of diphtheria varies from year to year, and local outbreaks are common. It behooves the profession to be diphtheria-minded if the occasional case is to be detected promptly and the spread of the infection prevented.

DOCTORS FOR ARMED FORCES

A FEW WEEKS ago a letter was sent by Dr. R. L. Sensenich, president of the American Medical Association, to approximately 7,000 physicians under the age of twenty-six, strongly urging them to volunteer for military service. Some 900 postal cards which accompanied the letters were returned, and about 500 requests for application forms for commissions have been received. This is not enough to meet the urgent need. About 2,000 doctors now on active duty will be released within the next few months, and more than this number of new enlistments will be needed, not only to replace those who will leave the service but to care for the expansion of the armed forces provided for by the Selective Service Act of 1948.

The names of those doctors under the age of twenty-six who have not responded to Dr. Sensenich's letter have been sent to the secretaries of the state medical associations, and personal contacts are being planned through county societies. If enough recruits can be obtained from this group under twenty-six, the necessity of a draft of the profession, a step which has never yet been necessary, will be obviated. The financial compensation of medical officers today is especially attractive. This, added to the stimulus of patriotic duty, should produce the desired response.

The drafted boys are doing their part under compulsion, it is true. Their medical needs must be provided for, preferably by volunteer enlistment of doctors or by draft. Patriotism is not limited to the emergency of war.

PRINCIPAL ORGANIZATIONS PROMOTING COMPULSORY SICKNESS INSURANCE

In order that our readers may know the principal organizations promoting compulsory sickness insurance and their personnel, we are listing them:

The Committee for the Nation's Health is located at 1790 Broadway, New York City. Dr. Channing Frothingham is chairman of the committee, and Michael M. Davis is chairman of the Executive Committee. Included on the committee are: Mrs. Eleanor Roosevelt, Gerard Swope, David Saranoff, Mrs. Gardner Cowles (a staff member of *Look* Magazine), Abe Fortas (a law partner of Thurman Arnold), and the presidents of the A. F. of L. and the C. I. O. The membership consists of some 2700 persons, 22 per cent of whom live in New York, and less than 8 per cent of whom are physicians.

The Physicians Forum is a group of physicians also working for compulsory government insurance. Dr. Earnest Boas of New York is chairman. According to Dr. Boas' testimony in Congress, the Forum has about 1000 members, of whom almost 600 are located in New York State and about 100 are located west of the Mississippi.

The Committee of Physicians for the Improvement of Medical Care, according to Dr. John Peters, consists of some forty physicians, most of whom are in the New York-New England area. Dr. Edward L. Young of Boston is chairman, and among the other officers are: Dr. Channing Frothingham, Dr. John Peters of New Haven, Dr. Ernest Boas of New York, and Dr. Dean Clark of New York.

The Committee for the Research of Medical Economics, also located at 1790 Broadway, New York, has as its chairman, Michael M. Davis.

The name of Dr. Boas appears on the membership of all four organizations; Dr. Peterson, on three; and Dr. Frothingham, also on three. There is an apparent interlocking of directors and members in the four organizations.

TELEPHONED NARCOTIC ORDERS

A. M. BANGS
District Supervisor, Bureau of Narcotics
Minneapolis, Minnesota

The Harrison Narcotic Law, as re-enacted in the Internal Revenue Code, is designed to direct the manufacture and distribution of narcotic drugs through medical channels to consumption for medical purposes only. These are the fundamental, underlying principles and objectives of the Federal Narcotic Law and the Minnesota Uniform State Narcotic Act. The related regulations designed to achieve this are clear and necessary elements in the suppressing of addiction to narcotic drugs.

Despite the clearness of the law and regulations, and the fact that they have been in effect for about thirty years, we still find entirely too many narcotic prescriptions in drug store files which were improperly executed by the issuing physician.

We also find a great number of notes and unsigned pieces of paper in drug store files that reflect the filling of telephoned orders for narcotic drugs. (Unless a prescription is properly written and signed, and for a legitimate purpose, *it is merely a piece of paper).*

Almost every day we receive complaints from druggists about physicians insisting by telephone that they supply patients with narcotics without a prescription.

This places the law-abiding pharmacist in an embarrassing position because, if he supplies the narcotic drugs without receiving a prescription first, he is definitely violating the law. If he shows reluctance to comply with the physician's telephoned request, the physician often becomes very indignant, and often tells the pharmacist "If you won't take it, I'll call a druggist who will," and in many cases is able to make his threat good because there are druggists, unfortunately, who will accept and supply narcotic drugs on telephoned orders.

The practice of telephoning narcotic prescriptions indiscriminately has presented a real problem of diversion of narcotic drugs to addicts.

The Bureau of Narcotics has encountered a great many instances where a drug addict telephoned a druggist, representing himself to be a physician, and caused the druggist to deliver narcotic drugs which were used only for the gratification of the addict and his associates.

By telephoning the druggist and representing himself as a physician, an addict recently obtained more than one thousand pantopon and morphine tablets from sixteen different drug stores on forty-five different occasions. A large portion of the drugs thus obtained were sold by the addict to other addicts at $3.00 to $5.00 per tablet. This demonstrates that if the telephoning of orders for narcotic drugs were permitted, much greater diversions would result.

The Physician Is Responsible

The Bureau of Narcotics and its field agents want to co-operate in every possible way with physicians and druggists in relation to the observance of the laws governing the dispensing of narcotic drugs, for we have a law to enforce and it is our duty to enforce it.

The Law Applies with Equal Force to Physician and Druggist

The physician is the party of original responsibility. There is no good reason why he should not obey the law and write and sign all of his prescriptions for narcotic drugs. If he does not, the conscientious druggist should absolutely refuse to accept his telephoned narcotic orders or improperly executed prescriptions for narcotic drugs.

Violations cannot be tolerated and the law must take its course when they are found.

Formal Requirements for Narcotic Prescriptions

1. The furnishing of narcotic drugs pursuant to telephone advice of practitioners is prohibited, whether prescriptions covering such orders are subsequently received or not, except that in a genuine emergency a druggist may deliver narcotic drugs pursuant to a telephone order, provided the druggist is supplied with a properly prepared prescription at the time of delivery.

2. A physician must not use his prescription form to obtain narcotic drugs for general office practice. Narcotic drugs desired for general office practice are obtainable on official order form from a qualified manufacturer or wholesale dealer. An order for narcotic drugs for general office practice, written on a prescription blank, is not a lawful prescription within the meaning of the law and can have no effect to validate the sale which is illegal.

3. A prescription for narcotic drugs shall be dated as of and signed on the date when issued and shall bear the full name and address of the patient, and the name, address, and registry number of the practitioner. A physician may sign a prescription in the same manner as he would sign a check or legal document as, for instance, J. H. Smith, John H. Smith, or John Henry Smith. Prescriptions should be typed or written with ink or indelible pencil; if typewritten, they should be signed by the practitioner. The refilling of a prescription for taxable narcotic drugs is prohibited.

4. A prescription, in order to be effective in legalizing the possession of unstamped narcotic drugs and eliminating the necessity for use of order forms, must be issued for legitimate medical purposes. The responsibility for the proper prescribing and dispensing of narcotic drugs is upon the practitioner, but a corresponding liability rests with the druggist who fills the prescription.

5. An order purporting to be a prescription issued to an addict or habitual user of narcotics, not in the course of professional treatment, for the purpose of providing the user with narcotics sufficient to keep him comfortable by maintaining his customary use, is not a prescription within the meaning and intent of the act; and

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

RURAL HEALTH ISSUE MORE CRITICAL NOW

Physicians are finding that the illnesses of their rural patients are being complicated by a new set of symptoms, labeled variously "compulsory health insurance," "government medicine" and "sickness insurance."

The rural population is looked upon by the socializers as a vast and fertile field for the sowing of collectivist ideas. The first crop they wish to reap is a system of governmentally administered medical and hospital care.

Fortunately, rural people for the most part are individualistic in character; agriculture is basically an illustration of private enterprise at work. Through such organizations as the Farm Bureau, they strive for voluntary co-operation to further common goals; through Blue Cross, Blue Shield and commercial policies, they have provided for the financial emergencies of sickness; by co-operative thinking they are seeking to solve many another problem of rural life which involves health and welfare.

More than 600 leaders from farm and health organizations met February 4 and 5 at the Palmer House in Chicago to phrase answers to the question, "How can we achieve better health for the people of rural United States?"

Points of view represented at the session, sponsored by the AMA's Committee on Rural Health, diverged from medical schools to milk producers' associations; but the concept of problems and the suggestions for solutions to those problems did not diverge so widely.

Occasionally a familiar phrase from the Ewing fantasy echoed through the meeting—"325,000 die needlessly every year," "medical care is beyond the reach of too large a segment of our population," "a system of compulsory health insurance would guarantee an even distribution of medical care."

But more typical was this comment:

". . . these conferences on rural health have set the pattern for people to get together to discuss openly what they should do to provide for their own needs and find ways of solving their own problems," pointed out Aubrey D. Gates, associate director of the Arkansas Agricultural Extension Service. "If a satisfactory program for rural health facilities is not worked out by the people themselves—both the lay and the professional groups—it is a fairly safe assumption that one will be developed by an Act of Congress to be administered by the federal government. To me, this is socialized medical care of the most damnable sort."

Agreeing with Mr. Gates, Mrs. Margaret K. Taylor of Washington, educational director of the National Co-operative Milk Producers Federation, added:

"We believe that improvement of community rural health can be made through a constructive program of education and service such as that being conducted by the American Medical Association through its Committee on Rural Health."

The Milk federation, a marketing organization for dairy farmers in forty-seven states, is conducting a four-point program for improved farm health:

"1. Encouragement of prepaid medical, hospital and dental care on a voluntary basis;

"2. Federal aid to improve health standards through education and research;

"3. An expanded school lunch program;

"4. Support of federal-state programs for the control and eradication of bovine diseases.

Distribution of medical care on a cold, matter-of-fact basis cannot be a success, the conference was told. Equalizing medical care by moving doctors about like chessmen does not take into consideration the doctor-patient relationship.

Said Dr. Ward Darley:

"Medical care, no matter how superior it may be from the scientific standpoint, cannot be truly effective unless the patient-physician relationship is such as to permit the physician to make the maximum use of his own personality as an agent of comfort and therapy."

Dr. Darley, executive dean of the health sciences and services, University of Colorado School

of Medicine, added a few comments on specialization, summarizing: "While this trend has added to the cost of medical care, as the costs of medical care have increased, so have our survival rates."

Farm safety and diseases whose symptoms and aftermaths are shared indiscriminately by mankind and animals came in for consideration by the conference.

Cautioning against undue complacency about the control of these man-animal diseases, Dr. H. B. Mulholland of Charlottesville, Virginia, said, "Education of farm people in the fundamentals of transmission of these diseases in animals and man is paramount, and constant vigilance must be maintained, even though some of them are seemingly well under control, else they will break out afresh."

Accident prevention was also accorded a position of prominence in the discussion groups. "Farm accidents are taking an annual economic toll of nearly one billion dollars," claimed Maynard Coe of Chicago, director of the farm division, National Safety Council. "Accidents to farmers cause enough lost time in a year to produce more than half the average annual wheat crop in the United States."

He reported that there are about 19,000 accidental deaths annually on American farms. More than one-third of these occur in homes, with falls, burns, poisons, suffocation, firearms and drowning the principal causes. "Agriculture is far behind most of the other groups in safety endeavors," he asserted. "Only recently has a beginning been made to reduce farm accidents."

Concluding the conference, the AMA Committee on Rural Health adopted a comprehensive program to bring a high standard of health and medical care to rural communities:

"1. State and public health services for general community hygiene and communicable disease control; public health nursing, well-baby conferences and clinics;

"2. The Hill-Burton Hospital Construction act operating where the people of a community demonstrate sufficient desire for such facilities.

"3. Medical scholarships provided by medical associations, Farm Bureaus and through legislative appropriations to be given to deserving boys and girls, without discrimination, for medical and nurses' education where they agree to practice for a time in rural areas.

"4. Agricultural school extension services where they utilize their home demonstration courses, 4-H clubs, health specialists whose special duty it is to organize health councils in the counties for the purpose of health education and where appropriate to apply for Hill-Burton facilities; the teaching of better farm methods, better soil conservation and soil building practices, better grain and productive livestock methods such as calf and pig clubs, five-acre club lots, better cost accounting and business method.

"5. Parent Teacher associations where they encourage school children examination for hearing, sight, heart, hernia, immunization, school hygiene, as well as physical education.

"6. Special health groups such as tuberculosis, polio, cancer, heart, which do considerable educating within narrow limits.

"7. The application of voluntary prepaid medical and hospital care plans to rural communities, taking into consideration that several of the large farm groups have their own indemnity prepaid medical and hospital plans.

"8. A promotion of state and county health councils, the medical profession acting co-operatively with organized farm groups and other civic, church and school organizations and special health groups for the purpose of health education and health activities of local character.

"9. A plan to bring the medically indigent, or low income, farmer into voluntary prepaid medical plans, which may involve some state financial aid.

"10. Use of the health education programs of farm groups.

"11. Encouragement of the civilian population, as distinguished from governmental official action, to help itself."

ECONOMIST SURVEYS HOSPITAL ACTIVITIES

Economics of the hospital system as he found them in New York and as they would apply elsewhere in the United States were reported by Eli Ginzberg, Ph.D., professor of economics, Columbia University, when he spoke at a meeting of the Council on Medical Education and Hospitals of the American Medical Association February 6, at the Palmer House, Chicago.

He came to the conclusion that hospitals could become a more efficient operation if more attention were paid to the administration and economics thereof. For example, he pointed out, hospital councils, tying in the facilities of a region, would eliminate the duplication and/or imbalance of facilities that exists in some areas now. "Hospital plans of the United States grew up in an era of free competition and no consideration was given to the location of nearby facilities."

Furthermore, he suggested that 70 per cent of nursing functions could be performed by nurses having nine to twelve months of training, provided that the remaining 30 per cent was taken care of by more highly trained nurses, following what he called the "teamwork approach."

COLUMNISTS LASH OUT AGAINST SOCIALISM

Some fifteen American newspaper columnists have lined themselves up against socialism as the onslaught against the first democratic defense—the private practice of medicine—proceeds.

Among the more recent expressions, in book form, is Lawrence Sullivan's *The Case Against Socialized Medicine* which he dedicates "To the men and women of American Medicine, who are too busy in good works to answer the slanderous darts of the bureaucrats."

PARENT TEACHER GROUPS SEEK CONTINUED AID

Minnesota Parent Teacher associations are asking for continued doctor co-operation in their "round-up" program which aims to have all children, entering school for the first time, examined by the family physician and their physical defects corrected, according to the doctor's advice.

The advisory committees of the state and national PTA Summer Round-Up are headed by practicing physicians and the program has the sanction of both the American Medical Association and the Minnesota State Medical Association.

St. Paul Cook Pleads Guilty to Charge of Abortion

Re. State of Minnesota vs. Gordon T. Berger.

On January 25, 1949, Gordon T. Berger, forty-one years of age, 1376 North Victoria Street, Saint Paul, entered a plea of guilty in the District Court of Ramsey County, to an information charging him with the crime of abortion. Berger was sentenced by the Hon. John W. Boerner to a term of not to exceed four years in a state penal institution, the sentence being suspended and the defendant placed on probation for four years.

Berger was arrested on November 4, 1948, with one Lula M. Sloan who stated that she was Berger's common-law wife. They were arrested at their residence 1376 No. Victoria Street, Saint Paul, following an investigation by Minneapolis and Saint Paul police officers of an abortion performed on a Saint Paul divorcee. The investigation disclosed two women at the home of the defendants who had been aborted the day before. The patients were removed to Ancker Hospital in Saint Paul, and the defendants placed in jail. On November 5, a complaint was issued against both Berger and his common-law wife charging them with the crime of abortion. Upon being arraigned in the Municipal Court of Saint Paul on November 6, the case was continued to November 16, for a preliminary hearing. Subsequently the case was continued to November 30, to December 20, and on January 3, 1949, both defendants waived a preliminary hearing and were held to the District Court for trial. On January 6, the cases were set for trial for January 25. On that date, Berger entered a plea of guilty, and the case against the defendant Sloan was dismissed on recommendation of the County Attorney of Ramsey County, when it was diclosed that her participation in the abortion work was merely to look after the patients after they had been aborted by the defendant Berger.

Berger claims that he was born at Harrisburg, Pennsylvania, February 22, 1907. At the time of his arrest he was questioned about his occupation and he replied: "abortionist." Berger stated that he had been performing abortions for about two years and that he made his living as a cook before going into abortion work. Berger performed the abortions by injecting a soap solution into the uterus.

Minneapolis Woman Pleads Guilty to Abortion Charge

Re. State of Minnesota vs. Elsie Mae Perreault

On January 17, 1949, Mrs. Elsie Mae Perreault, forty-two years of age, 2 South 11th Street, Minneapolis, was sentenced by the Hon. Levi M. Hall, Judge of the District Court, to a term of one year in the Minneapolis Women's Detention Home. The sentence followed the entering of a plea of guilty by the defendant on December 30, 1948, to an information charging her with the crime of abortion. In view of the fact that there was no evidence that the defendant had performed other abortions, the Court suspended the sentence and placed the defendant on probation for one year.

The defendant was arrested on December 7, 1948, by Minneapolis police officers when it was learned that a twenty-five-year-old unmarried Minneapolis woman was hospitalized at Minneapolis General Hospital suffering from the after effects of a criminal abortion. The abortion was performed on November 16, 1948, in the apartment of the defendant by the use of elm bark. $100 was paid the defendant for her services. The defendant admitted that she had no training as a nurse or midwife and stated that her knowledge about abortions was acquired by aborting herself in the same manner, on three occasions. The defendant is employed by a Minneapolis printing concern.

St. Paul Dentist Convicted of Abortion

Re. State of Minnesota vs. Earl S. Weber

On January 27, 1949, Earl S. Weber, fifty-two years of age, entered a plea of guilty in the District Court of Ramsey County, to an information charging him with the crime of abortion. Weber, a licensed dentist with an office at 424 First Federal Building, 5th and Cedar Streets, Saint Paul, performed an abortion on a twenty-eight-year-old unmarried Minneapolis woman for which he was paid the sum of $100. The abortion was performed by the use of a curette on January 18, 1949, at Weber's dental office. The patient became seriously ill and required hospitalization at Minneapolis General Hospital.

A plea for leniency was made to the Court on the grounds that Weber is one of four Negro dentists in Saint Paul and that his dental services are needed by the Negro population of the city. It was also stated to the Court that Weber had performed only one other criminal abortion, that one having been performed on a relative of the defendant. Judge John W. Boerner sentenced Weber to a term of not to exceed four years in the State Prison at Stillwater, stayed the sentence and placed Weber on probation for four years. Judge Boerner warned Weber that any violation of his probation would result in an immediate revocation thereof and that Weber would be taken to Stillwater to serve his sentence. Weber stated to the Court that he was born in Saint Paul and graduated from the School of Dentistry, University of Minnesota, in 1921.

Minnesota Academy of Medicine

Meeting of November 10, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 10, 1948. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 p. m. by the President, Dr. T. A. Peppard.

There were forty-nine members and two guests present.

Minutes of the October meeting were read and approved.

Dr. A. W. Ide read the following memorial to Dr. Robert Earl and a motion was carried that this be spread on the Proceedings of the Academy and a copy sent to the family.

ROBERT EARL—1872-1948

Robert Earl was born on a farm near Lansing, Iowa, on August 27, 1872. He was one of five children of Mr. P. O. Earl and Mrs. Hannah Anderson Earl.

Ten years after the birth of Robert, Mr. and Mrs. Earl moved with their family to Minneapolis, having decided to abandon farm life because Mr. Earl was afflicted with a heart murmur. This ailment was not fatal, however, for the father lived past his 97th birthday.

From the time of the move to Minneapolis, Robert Earl attended the public schools of that city, then the University of Minnesota, receiving his M.D. degree in 1896.

He was married in 1900 to Clara S. Swanstrom. He died on August 11, 1948, survived by his wife; a daughter, Mrs. James Slocum of Minneapolis; a son, Dr. John Earl of Saint Paul; five grandchildren; two sisters, Emily Earl and Hilda Anderson of California; and a brother, Dr. George Earl of Saint Paul.

Even a brief history of Dr. Robert Earl's life must emphasize the dual nature of his medical career. His activities as a practicing surgeon in Saint Paul reflect credit both on himself and on his profession. After his graduation in 1896 he served his internship at Bethesda Hospital, where he was influenced by his association with Dr. Edouard Boeckman and Dr. E. M. Lundholm. Partly as a result of their influence his interests were directed to the field of general surgery. After his year as an intern, he established himself in general practice. His formal training in surgery was continued in 1911 by a year of study in Europe.

In 1910 he was joined by his brother, Dr. George Earl. The partnership of the two brothers grew into what became the Earl Clinic. Dr. Robert Earl's son, Dr. John Earl, recently joined this Clinic.

The other major division of his medical career utilized an organizational and administrative ability in activities which had a profound and lasting influence on the community. He was president of the organization known as the Mounds Park Sanitarium, later known as the Northwestern Baptist Hospital Association. Under its original name this association sponsored and built the Mounds Park Sanitarium in 1906. The same organization, under its changed name and still under the Earl guidance, built Midway Hospital in 1926. He was also on a committee of three appointed by the Mayor of Saint Paul to aid in the location of what is now known as Gillette Hospital. He was active in varying degrees in all three of these hospitals after their construction, being a member of the staff of each.

Doctor Earl was a Diplomate of the American Board of Surgery, and was a member of the American College of Surgeons, the Western Surgical Society, the American Medical Association, the Minnesota State Medical Association, the Saint Paul Surgical Society, the Ramsey County Medical Society, and the Minnesota Academy of Medicine. His Inaugural Thesis for the Academy, entitled "Fractures of the Skull," was read on December 12, 1917, and published in MINNESOTA MEDICINE in July 1918. Other papers and frequent discussions were part of his active contribution to the societies of which he was a member.

By his surgical and organizational abilities and by his unfailing interest in the many activities in which he engaged, Doctor Earl established himself as a man of influence. His presence will be missed by the members of the Minnesota Academy of Medicine and by many others, but his influence will endure.

The Committee
ARTHUR W. IDE, *Chairman*
WM. H. HENGSTLER
C. C. CHATTERTON

Upon ballot, Dr. Walter P. Gardner, of Saint Paul, was elected a candidate for membership in the Academy.

Dr. William P. Sadler, of Minneapolis, read a case report on "Rare Types of Intra-Abdominal Bleeding."

RARE TYPES OF INTRA-ABDOMINAL BLEEDING

WILLIAM P. SADLER, M.D.
Minneapolis, Minnesota

There are many obscure causes of intra-abdominal bleeding due to hidden pathological states which severely test the diagnostic acumen of the most experienced. Even in the more usual and obvious diseases causing hemoperitoneum, the diagnosis is not always easy.

Among the commoner types of diseases causing bleeding intraperitoneally are: eroding primary or metastatic tumors of the liver, spleen, kidneys, pancreas, stomach, and bowel. Also, pathologic or traumatic rupture of a viscus, auto accidents, war injuries, industrial and athletic traumata, frequently cause this type of bleeding.

Other causes, less common, are, rupture of varices of and bowel. Also, pathologic or traumatic rupture of a viscus, auto accidents, war injuries, industrial and athletic traumata, frequently cause this type of bleeding.

Other causes, less common, are, rupture of varices of

the liver or round ligament, or of subserosal varices (omental, visceral and mesenteric); dissecting or luetic aneurysms of the aorta or superior mesenteric artery; angiomata of the liver and spleen, and rupture of the inferior epigastric vein.

Ordinary types of intra-abdominal bleeding of interest to the gynecologist are those due to ruptured Graafian follicles, corpora luteal cysts, strangulation of the ovary, tubes, and/or ovary and tube, ruptured ectopic gestation, endometrial cysts, and tubo-ovarian abscesses. Much less common is rupture of a broad ligament varix, rupture of a uterine vein during pregnancy or labor and rupture of a vein on a uterine fibroid from necrosis or stretching. Rupture of cesarean section scars and spontaneous rupture of the uterus during or before labor is not rare.

Spontaneous Splenic Rupture

So-called spontaneous rupture of the spleen is of interest to the internist, surgeon, gynecologist, neuropsychiatrist, otolaryngologist, and syphilologist.

In 1941, King reported the first case of spontaneous rupture of the spleen in infectious mononucleosis. In January, 1948, Timmes, Averill, and Metcalfe reported two cases with a review of the literature bringing the number of such cases to sixteen. Of these sixteen cases, a diagnosis of infectious mononucleosis was made in seven before splenic rupture, and in seven cases after rupture. The diagnosis was doubtful in the remaining two cases.

There were five deaths in this series, giving a total mortality rate of 31.25 per cent. Thirteen of these patients were operated upon with eleven survivals and two deaths. This shows an operative mortality of 15.38 per cent.

It is very probable that rupture of the spleen in infectious mononucleosis either spontaneously or due to minimal trauma may not be as rare as previously supposed. More alertness to the possibility of this disaster with its attendant high mortality in an otherwise benign disease, and prompter surgical intervention when diagnosed, will reduce the heavy mortality. While the spleen is enlarged, intra-abdominal strain should be avoided and abdominal palpation interdicted.

Rupture of the Malarial Spleen

Rupture of the spleen spontaneously or following minimal trauma occurs in many of the splenomegalies, fevers such as typhoid, and following influenza (one case), but the disease par excellence in which it occurs is malaria.

In January, 1948, Hershey and Lubitz reported a case of rupture of the malarial spleen and carefully reviewed the American and foreign literature. Their review brought the number of cases reported from 1917 to 1948 to sixty-four. They quote a review of Leighton, prior to 1917, in which seventy-two cases were reported.

Of Hershey and Lubitz's sixty-four cases, twenty-five splenic ruptures occurred in patients with naturally acquired malaria, while thirty-nine were recorded in patients with central nervous system syphilis who had been inoculated with malaria for therapeusis. Although this complication in naturally acquired malaria is considered rare, and is estimated by Manson and Bahr to occur once in one hundred thousand cases, it occurred three times in 30,000 malarial hospital admissions in the Canal Zone. It is a common cause of death in endemic malarial regions following trauma. It is said to cause 4.45 per cent of all malarial deaths in one section of India (Massari). According to Asteriades, allegedly normal, as well as malarial, spleens have ruptured during labor.

Other Splenic Ruptures

Several cases of spontaneous ruptures of so-called normal spleens have been reported. It is the author's view that some disease process or trauma is a factor in the rupture of these allegedly normal spleens.

McCarthy and Knapp reported two cases of splenic rupture in September 1944, one of which occurred in an infectious mononucleosis patient. (This case was not included in the review of Timmes, Averill, and Metcalfe in 1948.) Their second case developed in a patient in whom the pathologic diagnosis after splenectomy was "multiple hemangiomas of the spleen" with perforation of the capsule.

Case Reports

In the following report, the pathologist ascribed the cause of splenic rupture as probably due to rupture of a capillary cavernous hemangioma.

Case 1.—The case is that of an eighteen-year-old white girl who was admitted to the Minneapolis General Hospital May 15, 1938, because of pain in the lower abdomen, dizziness, nausea and vomiting during the ten hours previous to admission. Three weeks earlier she had developed pain in the right lower quadrant, accompanied by nausea and vomiting and was confined to bed for one week. At that time she came to the Receiving Department for examination. The gynecological staff diagnosed pelvic inflammatory disease and advised further bed rest. From then until admission to the hospital, she suffered with abdominal pain and occasional chills followed by fever. For ten days previous to admission, the patient complained of painful defecation. On the day of admission the patient went for an automobile ride, during which she became suddenly nauseated, started to vomit, and had to lie down because of weakness and dizziness. She became progressively weaker, and the abdominal pain increased. Her menses had been normal except for excessive flow and her last menstrual period had ended one week before admission. The patient had an abortion at the age of fourteen. She had had antiluetic treatments for the past six months. Past history and systemic history were otherwise negative.

Physical examination revealed that the patient was a well-developed, well-nourished, apprehensive, young woman. Her skin was pale, cold, and clammy. The head was normal. The lungs were clear. Radial pulse was not obtainable. Apical rate was 90 and heart tones were faint. The heart was otherwise normal. The blood pressure was 64/40. The abdomen was distended. There was marked tenderness and rigidity of the entire abdomen. Rebound tenderness was elicited. Pelvic examination revealed a moderate cyanosis of the vaginal mucous membrane, a small amount of mucoid discharge from the cervix; the fundus was in second degree retroversion. Marked tenderness was noted throughout the pelvis. A tender mass was in the right adnexal region. The left adnexa was indurated. The clinical impression at the time of admission was intra-abdominal hemorrhage from ruptured tubal abscess or tubal pregnancy.

The patient was admitted in shock at 1:00 a. m. Bedside x-ray indicated a paralytic type of ileus rather than

mechanical obstruction. The urine was negative. Hemoglobin was 44 per cent and leukocyte count was 32,000 with 85 per cent p.m.n.s., 14 per cent lymphocytes and 1 per cent monocytes.

Intravenous glucose was administered. At 2:50 a. m. the blood pressure was 106/60. A blood transfusion was started at 3:30 a. m., and 300 c.c. given. At 7:00 a. m., the blood pressure was 80/46. Another transfusion of 600 c.c. was administered by 8:00 a. m.; blood pressure at this time was 80/46. At 11:00 a. m., laparotomy was performed. The peritoneal cavity was "full of blood," but no bleeding point was found. A bilateral salpingectomy was done. The fallopian tubes showed chronic inflammation grossly and microscopically. The patient was given 1,000 c.c. of glucose at 2:45 p. m., and 1,000 c.c. of citrated blood at 4:00 p. m. At 5:00 p. m., 1,000 c.c. of 10 per cent glucose was again given, and at 10:30 p. m. another transfusion of 750 c.c. of citrated blood was given. The blood pressure at this time was 130/80 following a 600 c.c. transfusion at 1:40 a. m. on May 17; pulse 120 and good quality. At 4:30 p. m. of this day, 2,000 c.c. of 5 per cent glucose was given. The patient's condition remained critical. On the evening of May 18, respirations became labored. After a chest examination, a diagnosis of postoperative atelectasis and possible bronchopneumonia was made. She grew progressively weaker and expired at 7:38 p. m. on May 19, 1938.

The pertinent findings at autopsy were: The peritoneal cavity contains about 2,000 c.c. of dark liquid blood. The large and small intestines are distended with fluid and gas. The peritoneum is covered with organizing hemorrhagic fibrinous adhesions.

A search is made for the point of hemorrhage and a large mass of clotted blood is noted in the left subdiaphragmatic region. It extends below the costal margin and almost to the midline on the left. After the sternum and anterior portion of the ribs are removed to give better exposure, the extent of the clot is determined with some difficulty. The gastrosplenic ligament, the tail of the pancreas, the hilus of the spleen with the splenic artery and vein, and the gastric and renal surfaces of the spleen are all identified. The clot fills the entire space between these organs and the diaphragm. The spleen is embedded in the clot. The clot and spleen are removed in entirety. The mass weighs 1,000 grams. The splenic substance is intact. No definite point of bleeding can be identified on the surface of the spleen. Its diaphragmatic surface is covered by an organizing black clot over which is stretched the badly ruptured diaphragmatic portion of the splenic capsule. It is evident that the peritoneal hemorrhage originated from beneath the ruptured splenic capsule. Outside of the capsule is about 700 grams of fresher dark red clot. The spleen when freed from the clot weighs 170 grams.

Other pertinent findings were a small hematoma one centimeter in diameter on the upper surface of the liver, hydrothorax, atelectasis of lung, bronchopneumonia, and an incidental finding of a congenital anomaly, a double ureter of the left kidney.

Microscopic Findings.—"Study of a large number of blocks taken from the spleen yields little to explain the cause of hemorrhage. In only one small section is found an area probably representing a capillary cavernous hemangioma. But even here the findings are not absolutely conclusive."

*Case 2.**—L. H., a young woman, aged twenty-seven, was admitted to the hospital December 6, 1948, and was discharged well on December 21, 1948.

This patient gave a history of sudden onset of sharp abdominal pain on the day previous to admission. Pain was located in the epigastric region, right upper quadrant, and radiated to both lower quadrants and both flanks. She had bilateral shoulder strap pains. Pain was so severe she was unable to sleep that night. Pain was constant in the abdomen, but sharper at times. A physician, called to her home, made a probable diagnosis of appendicitis and recommended hospitalization. She delayed following his advice and entered the hospital the next morning. Pain had eased up somewhat and on admission she complained of a sharp shooting type of pain in the lower abdomen in the mid-line and suprapubic region. Her last menses was three weeks previously. Two days before admission there was slight spotting. There was no nausea or vomiting, but a loss of appetite. There had been two soft bowel movements the day before admission. She had had one pregnancy terminated at eight months due to eclampsia.

Physical findings showed the entire abdomen tender to palpation, most marked in the right lower quandrant and rebound tenderness was elicited throughout the abdomen. The pain was more severe in the lower abdomen. The uterus was described as slightly enlarged and a tender nodule was palpated in the right adnexal region. Hemoglobin on admission was 52 per cent and dropped to 45 within a few hours. White blood count was 10,600 with 72 per cent p.m.n.s.; blood pressure was 118/70. In view of a markedly tender lower abdomen, a tender right adnexal mass, slight cervical bleeding, signs of intraperitoneal hemorrhage with falling hemoglobin, a diagnosis of ruptured ectopic pregnancy was made and immediate operation advised.

At operation the abdomen was found to contain about a liter of blood and several small clots. The entire pelvis was normal. Exploration revealed a large clot about the spleen. The incision was enlarged, the spleen exposed, and a large hematoma was noted on its superior-posterior-lateral aspect. On palpation a large clot was evacuated from the upper pole of the spleen. There was another small subcapsular hemorrhage 2 centimeters in diameter on the anterior surface of the spleen. Splenectomy was done. The patient received three units of blood by transfusion during the operation.

Her postoperative course was uncomplicated and she was discharged on her fourteenth postoperative day.

Pathological Reports.—Specimen consists of spleen weighing 186 grams after formalin fixation. Covering a large portion of the anterior-lateral surface is a large subcapsular hematoma measuring up to 15 millimeters in thickness. The capsule over this shows irregular jagged lacerations. There are a number of sharply circumscribed, rounded dark purple nodules varying in size from a few millimeters to a few centimeters and extending deep into the pulp of the spleen.

Microscopic.— Sections of spleen show large areas of hemorrhage within the parenchyma. There is no intrinsic pathology in the pulp or malpighian bodies except for this hemorrhage. There is no evidence of tumor formation or angioma.

Diagnosis: Splenic rupture with intrasplenic hemorrhage.

Case 3.—This twenty-two-year-old woman was admitted to the hospital August 3, 1948, and was discharged August 21, 1948. She had been married for three weeks. Her last menses occurred July 15, 1948. She gave a history of experiencing sharp pain in the right lower quadrant during intercourse. Shortly afterward she developed abdominal cramps in the left lower quadrant. The cramps gradually improved. About six hours after coitus her cramps reappeared. She fainted. Her abdominal pains continued unabated. She became nauseated, vomited, was nervous and apprehensive. A family physician saw her, found a blood pressure of 60/0, advised hospitalization for "internal hemorrhage."

Physical findings on admission were temperature 98° F., blood pressure 96/68, pulse 84 full and regular. She appeared pale but was not in shock. Pelvic findings were a normal vaginal mucous membrane, firm cervix, closed, no bleeding or discharge. Corpus normal in size,

*Postscript case.

in mid-position and slightly tender. Right adnexa was negative. There was left adnexal tenderness but no mass. She was observed for two days. The hemoglobin dropped from 65 per cent on admission to 49 per cent in 48 hours; white blood count was 14,400 on admission with 82 p.m.n.s.

Operation was advised on August 5, 1948, under a tentative diagnosis of: (1) Ruptured ectopic pregnancy; (2) Ruptured follicle or luteal cyst.

Operation.—The abdomen contained about 800 c.c. of clots and dark liquid blood. The blood was removed and the pelvis was found normal. Further exploration showed the spleen, liver, pancreas, stomach, and kidneys normal. In the right renal gutter at about the level of the hepatic flexure, a large retroperitoneal hematoma was found and there was an ooze through the stretched peritoneal surface at this point. The hematoma was not evacuated. Oxycel was placed over the oozing area. The patient received 2 units of blood previous to and during operation.

She made an uneventful recovery and was discharged on her sixteenth postoperative day.

Discussion

Three case reports of rare types of intraperitoneal bleeding have been presented. The first patient with ruptured spleen may have had a rupture resulting from a hemangioma, although the pathologist does not indicate certainty. The gross description of the second spleen sounds like hemangioma, but the microscopic picture does not verify this diagnosis. Subsequent to operation in searching for a history of trauma, the second patient stated she was rough-housing with an eight-year old boy relative, but remembers experiencing no injury.

The third patient with retroperitoneal hemorrhage and subsequent intraperitoneal leakage may have had a varix rupture during the act of coitus. There was no obtainable history of any other trauma.

The operator's failure to explore the upper abdomen in Case 1 was due to an interpretation that the "bleeding was coming from the fimbriated extremities of the tubes," and "in view of the patient's critical condition." This error of omission resulted in a fatal outcome.

Summary

1. Many of the common and rare causes of hemoperitoneum are discussed.

2. Spontaneous rupture of the spleen in infectious mononucleosis may occur more frequently than has been suspected.

3. Rupture of the malarial spleen is discussed. It is noteworthy in the reported series that rupture incidence is much higher in patients inoculated with malaria than in those with naturally acquired malaria.

4. Two patients with ruptured spleen operated under the mistaken diagnosis of ruptured ectopic pregnancy are reported.

5. A case of retroperitoneal hematoma with intraperitoneal spilling is reported. The cause is unknown but probably was due to a ruptured varix during coitus.

6. A thorough painstaking exploration is always imperative when the usual sources of intraperitoneal bleeding are not found.

Dr. H. M. N. Wynne, Minneapolis, read his Inaugural Thesis on "Torsion of the Fallopian Tube."

Abstract

A presentation was made of three cases of torsion of the fallopian tube without involvement of the ovary. Slides of drawings and photographs of the specimens were shown. Pertinent literature on the subject was reviewed with a discussion of the symptoms, signs and differential diagnosis of the condition. The conclusion was drawn that a positive diagnosis of torsion of the fallopian tube without involvement of the ovary was extremely unlikely.

The meeting was adjourned.

A. E. Cardle, M.D., *Secretary*

Meeting of December 8, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 8, 1948. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 p. m. by the President, Dr. T. A. Peppard.

There were fifty-one members and one guest present.

Minutes of the November meeting were read and approved.

The following were elected as officers for 1949:

President, Dr. J. A. Lepak, Saint Paul.
Vice-president, Dr. William Hanson, Minneapolis.
Secretary-treasurer, Dr. A. E. Cardle, re-elected.

Dr. S. Marx White, Minneapolis, read the following memorial to Dr. J. C. Litzenberg.

JENNINGS CRAWFORD LITZENBERG
1870-1948

Jennings Crawford Litzenberg was born in Waubeck, Iowa, April 6, 1870. His paternal ancestors came from Germany in 1700. On his mother's side in the Crawford line coming from Scotland in 1730, were physicians in Cedar Rapids, Iowa, who undoubtedly influenced him much in the choice of his career. When he was six the family moved to Anamosa, Iowa, and when he was twenty, i.e., in 1890, his mother, then widowed, moved to Minneapolis.

Matriculated in the fall of that year in the University of Minnesota, his connection with and profound interest in that great institution covered a period of fifty-eight years, lasting to his dying day.

There was an interim of one year which he spent as Superintendent of Schools in St. Louis Park, but im-

mediately thereafter posts as Educational Director of Evening Schools of the Minneapolis Y.M.C.A. and employment by Dr. L. J. Cooke, Physical Director at the University of Minnesota, enabled him to enter the medical school from which he graduated in 1899. A year's internship in the Minneapolis General Hospital served as a foundation for general practice in Medicine.

Many months of study in Vienna in 1909-10 prepared him for specialization in Obstetrics and Gynecology and on his return he limited his work to that field. He was appointed Professor of Obstetrics and Gynecology and head of that department in 1914. Immediately thereupon he took a period of study and observation of many months in Vienna, Berlin, Glasgow and Dublin.

He retired from active participation in teaching in 1938 with the title of Professor Emeritus. He was a strong protagonist for the essential organic unity of the two fields represented in the title of his department. Responsibilities and honors came to him in profusion. He was elected president of the Hennepin County Medical Society in 1919 and of the Minnesota Academy of Medicine in 1932. He always considered these honors by men who knew him best as a source of greater satisfaction than the national honors that came to him.

He was elected chairman of the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association in 1928; president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons in 1933, and of the Central Association of Obstetricians and Gynecologists in 1939, and of the American Gynecological Society in 1940.

He was for ten years, 1930 to 1940, a member of the American Board of Certification in Obstetrics and Gynecology.

Litzenberg's great interest was in the saving of the lives of mother and child, and his teaching of undergraduates and graduate medical students reflected his interest. In addition to the many hundreds of the former graduated during his period of twenty-four years as chief of his department, about a dozen men received their special training and earned the Ph.D. degree under his direction.

His researches included the relation between low basal metabolism and infertility, the leukocytes in pregnancy, tubal pregnancy, and pregnancy in the tuberculous. Conservation of the child-bearing function was a major interest with him. He illustrated in striking fashion the dictum so often voiced by the late Dr. James E. Moore, "The true conservative is one who knows when to be radical."

This was manifest in his attitude toward heart disease in pregnancy. The writer of this sketch well remembers an occasion in about 1920 at the University Hospital. He was asked by Litzenberg to see four women in the obstetric wards who were presumed to have heart disease and the obstetrician wished to know if any of the quartette could be carried to term with safety. Older members of the Academy will remember the readiness with which at this period abortion was recommended in the presence of heart disease even though often minor in degree. As a result of the study then made, the opinion was recorded that three of the four, with proper management, could probably be carried through. This seemed to delight our friend. The outcome justified the attempt, and from that time on close co-operation between the obstetrician and the cardiologist has resulted in the saving of many hundred infant lives.

His "Synopsis of Obstetrics" was published in 1940, and translated into Spanish by Professor De Los Reyes in 1941. A second edition appeared in 1943.

He has been given the major credit by his colleagues in obstetrics for the remarkable reduction of maternal mortality recorded in this area beginning with 1920. In that year about 15,000 women died in the nation as a consequence of child bearing. The national and Minnesota rates were about seven deaths for every one thousand live births. When Litzenberg retired in 1938 Minnesota had the lowest maternal mortality rate in the nation. In 1947 Minnesota can boast of a record of 0.6 maternal deaths per one thousand live births. Dr. Ehrenberg, one of his specialty students and a colleague, states that this is the lowest ever recorded in the country, if not in the world.

Characteristic of Litzenberg's spirit, however, is a disclaimer in a brief autobiographic note which reads:

"I have been given too much personal credit for the improved teaching of obstetrics and gynecology in our Medical School. My staff deserves most of the credit for all members were in accord in a determined joint effort to improve the teaching so that all graduates would be constantly conscious of the dangers of child bearing and their duty to reduce them, i.e., the 'philosophy of conservative obstetrics.'"

During Litzenberg's incumbency his department in the Medical School did not require full time and he had his private practice first with a small staff of associates in his specialty. In 1921 he joined a group of men who for the most part held part-time teaching positions in the Medical School, to form the Nicollet Clinic for group practice. From this connection he retired December 31, 1947, and then only when ill health overtook him.

He was much sought in consultation and always spent freely his time and wise counsel.

He was for many years a Trustee of the First Baptist Church of Minneapolis.

A fine oil portrait of "Litz" by Edward Brewer was presented to the University by about two hundred and fifty of his colleagues at the time of his retirement from the University in 1938. It hangs in his former department.

Words by those of us who knew and loved him might be extravagant. Two evaluations by University Presidents under whom he served will not be so considered.

George Edgar Vincent wrote:

"I think of you with pleasure and gratitude. You were always calm, wise, humorous, and a steadying influence. You had ideals of research, teaching and organization to which you were quietly but steadfastly loyal. In times of stress and strain you kept your head and your temper. You will carry with you the assurance that you have played an important part in making the University of Minnesota Medical School one of the best in the country."

Lotus D. Coffman wrote:

"In recognition of your long and distinguished service the President and Board of Regents express their gratitude, esteem and affection. Your name is already on the roll of honor of those who have contributed to the development of a great University. You have served the University notably and well. Your tolerant optimism and intelligent devotion to your work have increased your usefulness far more than you ever suspected.

You have done a good job."

Dr. Litzenberg died August 15, 1948, after two hours' acute illness, of coronary occlusion.

A colleague in his specialty has written: "The Chief is gone! To us who sat at his feet there can be no other Chief. He lighted a torch which we have striven to carry. He personified a great spirit and growth in obstetrics and gynecology. Through the medium of his own idealism he represented an ideal. He was Litzenberg—jocularly translated from German into English by himself, 'A light in the mountains.' A bright light on a lofty height." S. Marx White

---

Dr. E. V. Goltz, Saint Paul, read the following Memorial to Dr. Alfred Hoff.

ALFRED HOFF
1883-1948

Dr. Alfred Hoff died suddenly October 9, 1948, at his home following an illness of several months.

He was born March 9, 1883, in St. Paul. He received his preliminary education in the schools of Saint Paul and was graduated from Cleveland High School in 1901. After working in the auditing department of the Northern Pacific Railroad for a time, he enrolled in the University of Minnesota, receiving his Bachelor of Science degree in 1908 and his Doctor of Medicine in 1910. He was a member of the Nu Sigma Nu fraternity and was elected to the Sigma Xi and Alpha Omega Alpha honorary fraternities.

Dr. Hoff served his internship at the City & County Hospital in 1910-1911 and continued his connection with this hospital in various capacities, chief of staff and at the time of his death he was chief of the medical section. In 1926, he took postgraduate work at the University of Vienna. On his return to St. Paul he confined his practice to Internal Medicine.

Dr. Hoff served as Chief of Staff of St. Luke's Hospital and was a member of the Board of Directors of this hospital.

Dr. Hoff was a Fellow of the American College of Physicians, certified by the American Board of Internal Medicine, also a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a member of the Minnesota Society of Internal Medicine and the Minnesota Academy of Medicine. He became a member of this Academy in 1935.

Dr. Hoff was married December 1, 1926, to Miss Marjorie Monkhouse. He is survived by his wife, son John and daughter Mary Patricia; also by two sisters and one brother.

Dr. Hoff was an ardent student in many phases of medicine. He devoted considerable time to the training of the intern staff and nurses at the Ancker and St. Luke's hospitals. He was held in respect and esteem by his associates for his professional ability and integrity.

The scientific program followed.

PRE-FRONTAL LOBOTOMY IN EIGHTY CASES

H. B. HANNAH, M.D.
Minneapolis, Minnesota

Therapy has always been a very intriguing subject in the practice of medicine and in more recent years in the practice of psychiatry. This evening I am going to call your attention to the various procedures in therapy which have occurred during the past thirty years.

In 1919 I went to work as a technician in a fairly large eastern sanitarium. We had about two hundred patients and each patient had a private room. The buildings were well constructed and well furnished; the grounds were beautiful and the food was excellent. There were four well trained psychiatrists and three consultants who came every day. Rounds were made twice a day and a staff conference was held once a week. An attempt was made to make a differential diagnosis as to the type of psychosis and a prognosis was given to the family. The treatment consisted of good nursing care, looking after the elimination, good food, sedatives, outdoor exercise, if possible, and hydrotherapy, if the patient was excited. Also, every effort was made to prevent the patient from injuring another patient or from injuring himself. The only specific therapy that I could see at that time was the use of chemicals in the treatment of syphilis.

In the early 1920's Wagner von Jauregg introduced fever therapy in the treatment of paresis. It was claimed at that time that early cases of paresis would be greatly benefited by fever therapy even after the onset of the symptoms and that better than one out of three went into a remission. As you know, fever therapy has continued to be used not only in the treatment of paresis and central nervous system lues, but also as a preventive measure.

Also, during the 1920's psychoanalysis began to be very popular and this was particularly true along the Atlantic seaboard. Of course, it has its greatest value in the treatment of the so-called psychoneurotic group or the so-called nervous tension state. A physician cannot become a psychoanalyst unless he has himself been analyzed and is free of his own hidden emotional conflicts. Psychoanalysis is a long tedious procedure and the average citizen does not have the time or the money to be subjected to this procedure. The period of time is anywhere from six months to eighteen months. As one of my colleagues once said, it seems to never end.

In 1928, at a meeting of a neuropsychiatric association at Madison, a patient with catatonic dementia praecox

was stimulated with carbon dioxide or was permitted to inhale an excess of carbon dioxide and then got up from his chair, walked around, opened his eyes, and answered questions. However, this only lasted for a short period and then he went back into his catatonic stupor. Several other similar experiments were being conducted at Madison with other cases of catatonic schizophrenia.

In 1935, Manfred Sakel released his first work on the treatment of functional psychoses with insulin shock. He reported a very high percentage of recovery in Manic depressive, schizophrenic and involutional psychoses. The psychiatric world was electrified and everyone began to use insulin shock therapy. However, clinical workers in this country and abroad could not duplicate the wonderful results reported by Sakel in the treatment of schizophrenia. However, this stimulated thinking from the standpoint of the organic approach to the treatment of the psychoses of the so-called functional type.

A couple of years later, Meduna reported his series of cases treated with the camphor derivative of metrazol. Metrazol was rapidly injected into the veins and the patient had a severe convulsion. There was much controversy as to whether metrazol was of any greater value than insulin shock therapy. The convulsions with metrazol were so severe that many fractures and dislocations occurred. There is no doubt that the length of time of recovery in the depressions and in the manic attacks was greatly reduced. Also, the patient with acute schizophrenic episodes did much better as far as remissions are concerned with a combination of metrazol and insulin shock therapy.

It was in 1938 or 1939 that two Italians, Beni and Cerletti, released their work on physical shock therapy by means of electricity. The results obtained with electric convulsive shock therapy have been gone over many times in literature and I am not going to spend any further time with this subject this evening.

In 1936 Egas Monas first reported the technique used and the results obtained in twenty cases of prefrontal lobotomy. Since that time there have been a large number of reports by neuropsychiatrists and neurosurgeons in this country as to the results which they have obtained.

Freeman and Watts, of Washington, D. C., have pioneered the operation of prefrontal lobotomy for mental abnormalities and have been very enthusiastic over their results. Magnus Peterson, of the Rochester State Hospital, in Minnesota, has also been very active in this field.

One of the most extensive reports was in 1947 from London, in which 1000 cases of prefrontal lobotomy were studied. The patients were all in mental hospitals and had been there from one year up to twenty years. Thirty-five per cent of the patients were discharged as recovered or improved; 32 per cent remained at the hospital as improved, 25 per cent remained in the hospital unchanged, and 1 per cent was worse following the operation. Death followed 5 per cent of the cases treated. Hemorrhage was the chief cause of death. Fits were reported in 3 per cent following operation but most of these had but one fit. In this series 60 per cent of the total treated were in the schizophrenic group and 23 per cent of this group were discharged as recovered or improved. The manic depressive group accounted for 25 per cent of the cases, and 50 per cent of this group recovered. Patients whose attacks had persisted for less than two years formed one-fifth of the patients treated and the discharge as to recovered or improved in this group was 58 per cent.

Social behavior was studied in 958 patients after surgery. Of these 244 were as before; 295 were milder; 165 were co-operative; 244 were living as citizens from the industrial and social standpoint, and eleven were worse.

An analysis of certain symptoms also was made. Delusions were gone in forty-six per cent of the patients. The hallucinations were definitely less in 30 per cent. It was very significant that the depression had disappeared in 83 per cent. Eighty-seven per cent had lost their agitation. In 57 per cent the excitement had disappeared or become less. Approximately 70 per cent had lost their obsessions.

Within the last three years we have had prefrontal lobotomies performed in eighty of our patients. Forty-two per cent of these were in the schizophrenic group, and approximately 75 per cent of the schizophrenics were of the paranoid type. These patients had been ill from one to eight years. Thirty-eight per cent were in the psychoneurotic group who suffered from obsessive compulsions. Eighteen per cent were suffering from depressions which had not recovered over a period of years. We had one patient with a chronic maniacal type of reaction and one patient with intractable pain from a carcinoma of the prostate which had metastacized into the spine. This last patient got no relief from his pain from the lobotomy operation.

In our series, we have not had any deaths. Most of the patients are up out of bed within twenty-four hours, and all of them have been up and around within seventy-two hours. The only complaint on the part of the patient has been of some headache or dizziness for a couple of days. A few of the patients have had some vomiting for twenty-four hours. We have not had any hemorrhages or any infection.

It is always difficult in this type of work to accurately evaluate the improvement average. If a patient can make a satisfactory economic, or what might be called an industrial and social adjustment, and get along without help of an institution or medical attention, then I feel that this individual has made satisfactory improvement or recovery. Such improvement has occurred in at least 75 per cent of our patients up to this time. I know you will be interested in what happens to the patients who have not improved. The chief symptoms seem to be lack of ambition, slowness, inertia, lack of desire or urge to work, and a willingness to sit around and do nothing. There is no deterioration in the intellectual level and most of the relatives describe the situation as one of laziness. Also, some of these patients become very irritable and cross if they are urged to extend themselves or look after themselves or do any work. It is difficult for me to understand why we get poor results in some of these cases.

I feel that we can draw the following conclusions at the present time:

1. Prefrontal lobotomy has been a rather simple operation as far as the patient is concerned. Ninety per cent of the patients have been able to get out of bed the day following the operation and, outside of a mild to moderate headache for a couple of days, they have had no other physical complaints. Complications are certainly rather infrequent and we have had no deaths so far in our series. Of those patients who made an eventual substantial recovery, 50 per cent were very slow and showed lack of initiative and had no urge to do things from several weeks up to several months. However, this slowness and lack of initiative gradually disappeared in all except 25 per cent of our patients.

2. Remarkable improvement in behavior has followed in all of our patients. This has been particularly true in the paranoid group. This improvement in behavior followed immediately after the surgery.

3. We are frequently asked the question as to what the result will be in ten to twenty years from now. Will there be a loss of some of the finer mental qualities? Up to the present time, we have not seen any intellectual deterioration but further study and observation for a period of years will certainly enlighten us further.

4. We do not feel that this operation should be carried out without careful consideration of each individual patient by experienced physicians who have had training and are experienced in the field of psychiatric medicine.

(Dr. Hannah presented two patients who had made a recovery.)

Discussion

Dr. W. H. Hengstler, Saint Paul: I want to express my personal appreciation to Dr. Hannah for his paper. I think it was very fine. My own experience in recommending lobotomy has been more limited. Dr. Ritchie has done some for us. The chief thing about it is that it now offers us something beyond shock therapy. We have been blocked off after we had given psychotic patients a certain amount of psychiatric care. Lobotomy offers these people something to hope for after some time. It also offers the State something, in that such a high percentage of patients who have lobotomy operations are able to leave the institutions and go back home at least, if not amenable to economic and social adjustment. The public gets the idea that everybody should have a lobotomy and get well. I think that is the danger as it is in any treatment which is not as yet completely standardized. I think Dr. Hannah's cases have proved that this is something which is very beneficial, and in the future we shall be able to establish certain standards by which we can go. They must be cases that have been psychotic for an extended period of time—three to five years—before lobotomy is attempted as a last procedure. I do believe that, as Dr. Hannah says, the family should be advised to have this operation done, assuming that all other methods have failed.

Dr. Wallace P. Ritchie, Saint Paul: The results that Dr. Hannah and Dr. Buchstein have had are certainly excellent and one could ask for no finer results than the two cases that were shown this evening.

We are really indebted to the two chimpanzees, Lucy and Becky, for the development of prefrontal lobotomy. These chimpanzees were used by Dr. John Fulton and his co-workers at Yale University and it was found that they were exceedingly excitable during their testing and at one time they became so irritable because they could not perform certain tests it was feared they might have nervous breakdowns if the examining was carried further. Prefrontal lobotomies were done on both these chimpanzees and, following this, they became much more amenable to testing. They strove to carry out their tests, but if they missed one they did not seem to be bothered by it.

Mechanically, the prefrontal lobotomy is not difficult: it is merely sectioning some of the white fibres from the frontal lobes which go to the thalamus.

In the selection of patients, the utmost care must, of course, be used. Usually in the psychotic patient, who has had years of treatment without avail, there is no question about the advisability. It is in the severe psychoneurotic patients that the extreme care must be taken, as, in my experience, patients are somewhat superficial in their attitude toward their life following the procedure. It is, therefore, truly an operation of last resort, in my opinion, and should never be done unless all other treatment has failed and life is unbearable for the patient.

Dr. E. M. Hammes, Saint Paul: Dr. Hannah has so fully covered the subject that there is very little to add. However, I feel it might be of interest to add how insulin and metrazol shock treatments came about. In the course of treating drug addicts and alcoholics, Sakel observed that, if he gave them moderately large doses of insulin also, the nervous manifestations were less pronounced. From this he reasoned that perhaps he might get some beneficial results with the use of insulin in psychotic patients. Fortunately, his first few patients responded satisfactorily. Meduna noted what is generally known, that epileptics very seldom suffer from a somatic psychosis. Because of that, he reasoned that perhaps the somatic psychosis would respond satisfactorily to convulsions produced by drugs. He first began to use metrazol and had satisfactory results. It was later found that the convulsions with metrazol were very severe and patients developed undue emotional reactions and fears. Gradually convulsions were produced in these patients by use of electric shocks. Judging from a fairly large experience with these treatments, we feel definitely that the percentage of recoveries is greater and the period of hospitalization is shortened. The most important question, however, is—How permanent are these results? Unfortunately the recurrence in these psychoses with the various forms of shock treatments is about as frequent as it was before they were used. The addition of psychosurgery to the therapeutic armamentarium has been another additional and very important help. We have had some very nice results in cases associated with noticeable depression, also a considerable amelioration in some of our chronic schizophrenics whose outstanding symptoms were vicious and destructive tendencies.

The meeting adjourned.

NON-OPERATIVE DECOMPRESSION OF THE INTESTINAL DISTENTION OF BOWEL OBSTRUCTION AND RELATED DISEASES

(Abstract)

J. H. STRICKLER, M.D.
Minneapolis, Minnesota

Most surgeons agree that severe or prolonged adynamic ileus is best treated by long intestinal intubation and suction. However, the treatment of acute mechanical obstruction is a subject on which some difference of opinion exists as to whether operation should be performed at once or after preliminary intubation and decompression has failed to relieve the obstruction. All agree that even a reasonable suspicion of strangulation of bowel is an acute surgical emergency.

Particularly in the present era of safe surgery and low risk of anesthesia—a prolonged period of decompression is undesirable whether the obstruction is to be treated by suction alone or as preparation for operation. Since the mortality from obstruction rises after a period of twenty-four hours and is especially high after seventy-two hours, the success of intubation treatment depends upon the rapidity with which it can be instituted. Such methods as inserting the tube blindly and waiting for passage, or waiting twelve to twenty-four hours before employing fluoroscopic aid, must be considered as only adding to the mortality and morbidity rates. One must establish an arbitrary short trial period after which, if intubation has not been successful, it should be abandoned. In this series 44 per cent of the cases of obstruction were intubated in thirty minutes or less and little further was accomplished after one hour. Therefore a trial period of one to two hours should be adequate. By adhering to such a policy and by the use of the technique and tube to be described, intubation treatment should still have an important place in the treatment of bowel obstructions. The patient can be evaluated more carefully and the surgical risk lessened by restoring physiological balance by means of decompression.

Reports on the general use of the Miller-Abbott tube indicate that failures and slow pylorus passage rates are discouragingly common. It is with such facts in mind that a search was made for an improved tube and a more reliable technique so that the long tube decompression would still have its proper place in the treatment of bowel distention and the employment of intubation would then improve the results. Wangensteen warns that the practice and employment of suction as a test procedure to indicate whether operation will be necessary leads only to a deferment of appropriate treatment.

Dr. Strickler is a Fellow, Department of Surgery, University of Minnesota Medical School (by invitation).

In 1944 John Wild of England published a description of a plastic tube with mercury-containing gravity director head and a bolus balloon. In an early series of twenty successive cases, without the aid of fluoroscopic guidance, Wild achieved an average passage time of 57.2 minutes for the tube to reach the second portion of the duodenum as confirmed by x-ray plates. Since that time the tube design and passage technique have become standardized. This technique and an evaluation of clinical results in 100 consecutive intubations on all types of intestinal distention will be presented here.

All intubations should be done with the aid of fluoroscopic manipulation and observation. Prior emptying of the stomach by suction will save time during passage of the long tube. The full, decompensated stomach associated with intestinal distention will then have had an opportunity to regain tone and motility essential to passage of the tube through the pylorus.

Duodenal Catheterization

Standard technique for the passage of Wild tube or other types of long intestinal tubes with a mercury gravity director head and balloon bolus with fluoroscopic aid:

1. Two per cent Pontocaine solution is applied to the nose.
2. With the patient lying flat on his back, place balloon of the tube at the tip of the xiphoid and measure the distance to the nostril. Place a tape marker on the tube at this point.
3. Stuff lubricant into the nostril and lubricate the mercury sack and balloon.
4. Milk the mercury sack into the nostril with the thumb and forefinger until all of the balloon has entered nostril.
5. Place the patient in the sitting position, leaning to the left, resting on the outstretched left arm.
6. Guide, do not push, the tube into the nostril as patient swallows it. Sips of tepid or warm water may be used if desired. Stop as tape marker reaches the nostril.
7. Inject air (usually 500 c.c.) into the stomach through the suction tube by means of a syringe. If the patient belches or complains of epigastric pain, stop at that point. In the presence of severe distention or cascading, 800 to 1000 c.c. of water may be needed to negotiate crossing of the stomach.
8. Place the patient on the right side, in about the half prone position.
9. Pass the tube 8 to 10 inches farther. This places the tip at the pylorus with enough slack to enter the duodenum.
10. Wait ten minutes and check by fluoroscopy.
11. If the tip is in the first portion of the duodenum, tilt the fluoroscopic table to 45 degrees, feet down; check each minute or two by a brief glance, until the tip is in the lower part of the second portion of the duodenum. Then insert 10 c.c. of air into the balloon.
12. Turn the patient to the left with fluoroscopic table flat until the tip passes the ligament of Treitz.

Fig. 1. Demonstrating the proper amount of slack tube in the stomach. Although the gravity director head is in the second portion of the duodenum, the bolus balloon is not far enough advanced to be inflated without fear of pulling the tube back into the stomach. Number 1 is placed to the right of the small metal insert in the end of the airway tube at the point of attachment to the bolus balloon. Number 2 is to the right of the metal sleeve which supports the bilaterally placed holes in the Koroseal suction tube. Number 3 is mercury within the closed gravity director head sack.

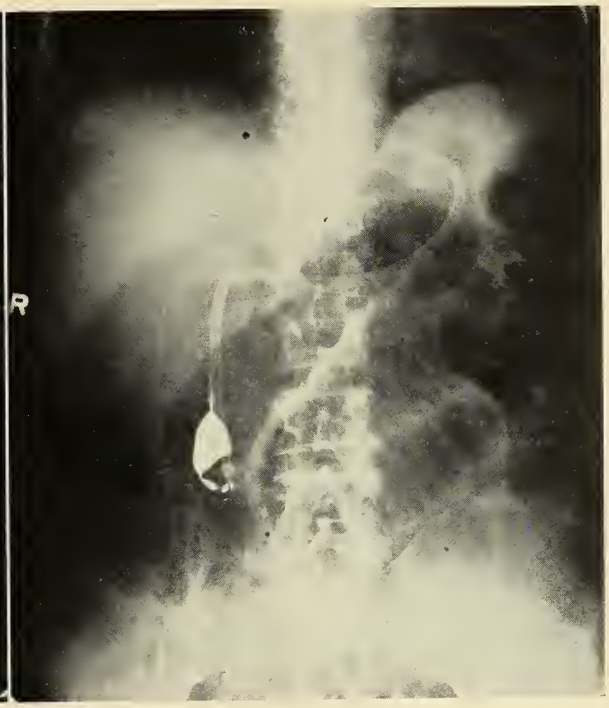

Fig. 2. The tip of this tube is low in the second portion of the duodenum. At this point the bolus balloon may be inflated with 10 c.c. of air and the patient turned on the left side. Although it is desirable to have the tube beyond the ligament of Treitz before discontinuing fluoroscopic manipulation, this position assures one that the intubation is successful and that decompression will begin.

13. When the balloon has passed the ligament of Treitz, withdraw air and refill to a total of 20 c.c. of air.
14. Check with Bucky film to make certain of position.
15. Return patient to bed and write orders to have tube advanced four inches each hour. Ascertain proper functioning of suction.
16. Check position at least once daily to be sure that the tube is not arrested over twenty-four hours in one position.
17. When the tip of the tube ceases to travel or the desired distance has been achieved, deflate the balloon.
18. Obtain check films each three to four days and inspect mercury sack for signs of distention from infusion of gas into the sack.

For Passage in Bed.

1. After the tip has been passed to the pylorus, elevate the foot of the bed to an angle of 45 degrees for half an hour. This accommodates for a saccular stomach and/or a high duodenal cap.
2. Then raise the head of the bed on two-foot shock blocks, or crank the head of the bed to 45 degrees for a half hour. Get check film and proceed as previously outlined.

For Passage in Gastric Resection Cases

1. After passage through the nose, keep the patient in the sitting position, leaning far to the left, until the tip of the tube has passed 12 to 18 inches beyond the xiphoid.
2. Do not use air in recently operated patients.
3. In the seriously ill, pass the tube with the patient lying on the left side with the head of the bed elevated.
4. Get a check film. If the tip of the tube passes to the left lateral wall and down near the iliac crest, inflate the balloon with 20 c.c. of air and have the tube advanced four inches each hour as in other cases.

Additional General Comments

If after five to ten minutes of fluoroscopic observation the tube has failed to pass the pylorus, put the patient to bed on the right side. Three to 5 c.c. of air in the balloon may help its passage. Recheck with films at intervals, depending upon the urgency of the case. Passage is usually accomplished in three to six hours.

Do not sedate the patient prior to passage.

In very old, weakened, or overly sedated patients, it is best to pass the tube into the esophagus with the patient flat on the back.

If the plastic tube is not sufficiently well visualized under fluoroscopy and the question of looping or knotting arises, 25 c.c. of thin barium may be put in under fluoroscopic vision until the barium column arrives at the tip of the tube. The barium should be withdrawn before sending the patient to bed.

Before giving up fluoroscopic trial the patient should be placed on the abdomen for five to ten minutes, head down about 20 degrees for five to ten minutes. Check the position of slack tube in the stomach, leaving only enough to follow the greater curvature.

If the tube fails to pass out of the fundus and extreme distention is present, a gastric balloon may be necessary to force the tip of the tube to the pylorus.

During air injection, if the patient belches on 50 c.c. of air, the tip is either in the esophagus or in a greatly compressed stomach. In such an instance, a gastric balloon likely will be needed.

In adynamic ileus, when the tube has entered the duodenum, a gastric suction tube should be inserted through

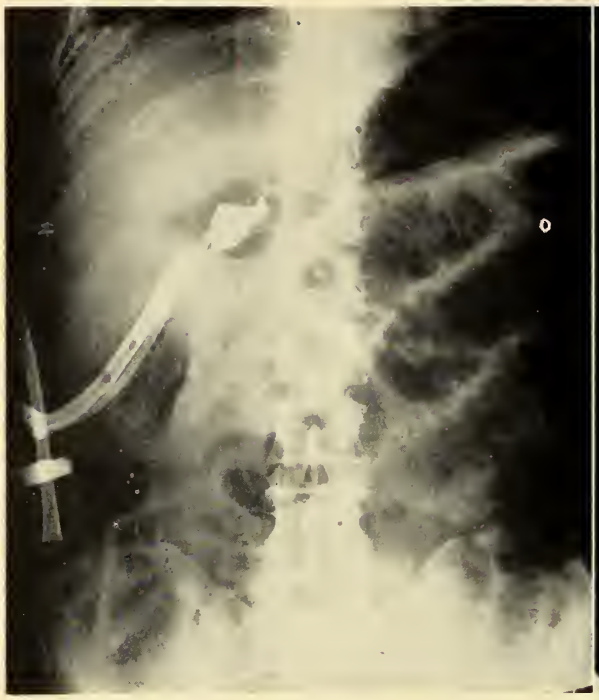

Fig. 3. Air injection technique. The tip of the tube is probably within the antrum. The two tubes on the right are air vent drainage tubes.

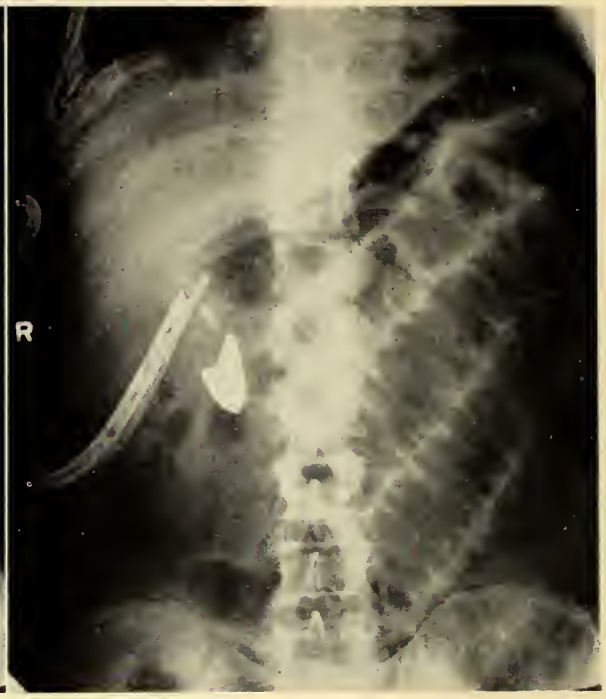

Fig. 4. The tube has passed through the pylorus, through the bulb, and now lies in the upper second portion of the duodenum. The time interval between films was one hour.

the other nostril into the stomach to prevent redistention above the advancing tube.

In a patient with active peristalsis the tube should never be taped to the nose when the balloon is inflated, for the sawing motion caused by peristalsis tugging on an anchored tube may cause esophageal erosion at the level of the cricoid cartilage and consequently a laryngeal inflammation and stenosis.

A word of caution should be added regarding the insertion of mineral oil down the tube. Oil will damage the latex rubber gravity head and balloon and the mercury sack may rupture as it is pulled out of the nostril. Aspiration of mercury is the only serious complication from breakage of the gravity head.

If one is uncertain as to whether the tube is in the stomach or third position of the duodenum, thin barium can be injected under fluoroscopic vision. Ten to 15 c.c. is usually sufficient to demonstrate valvulae conniventes.

In this series of 100 cases, forty-one were instances of acute obstructions on admission to the hospital, forty-three were intubated for postoperative distention, eight for adynamic ileus not related to prior operation and eight for prophylaxis prior to resection and anastomosis of non-obstructing colonic lesions.

In thirty minutes or less, the tube tip was placed low in the second portion of the duodenum in 44 per cent of patients with acute obstruction, 30 per cent of those with post-operative distention and 47 per cent of those with a gastroenteric stoma. As compared to Beverley Smith's series of 1,000 cases of Miller-Abbott intubations, this series has a 50 per cent successful passage rate in the period up to three hours of trial, whereas Smith reports 9 per cent.

Of the 18 per cent failures in this series all but 5 per cent were due to impossible situations such as mechanical obstruction at the pylorus due to carcinoma or ulcer, postoperative vagotomy, decompensated stomach and pylorospasm, mesenteric thrombosis, bile peritonitis in severe biochemical imbalance, and discontinuance of intubation treatment under one hour, or before the position of the tube could be proved by x-ray.

Twenty-two per cent of patients with primary obstruction were treated by suction only, and 81.4 per cent of those with postoperative distention were managed by intubation and suction only. In the obstruction group 73 per cent either had no operation or were operated upon after decompression and hydration had been accomplished.

Decompression was accomplished in less than twelve hours in 42 per cent of patients with cases of acute obstruction but in only 11 per cent of the instances of postoperative distention.

There were two cases of proven, definite and severe generalized peritonitis on whom intubation was successful and decompression was achieved, demonstrating contradiction to the opinion of some authors that suction decompression in such cases is impossible.

After elimination of hospital deaths occurring long after decompression and those due to terminal carcinomatosis unrelated to distention, the mortality rate was found to be 7.3 per cent for obstructions, 12.5 per cent for adynamic ileus not related to prior operation, and 11.6 per cent for postoperative distention of such severity as required long intestinal intubation. The total group mortality was 9.0 per cent.

Wild Tube Advantages

The Wild tube has the following advantages over the conventional Miller-Abbott tube:

The Wild tube is of plastic material, dri-film treated and is less irritating than rubber.

The aspiration lumen is larger and plugs less easily.

The terminal hole distal to the bolus balloon assures suction ahead of the balloon so the tube will not be pushed back by reverse flow. Multiple aspiration holes tend to become plugged distally and suction becomes effective only at some distance behind the balloon.

The mercury gravity director head acts as a leader device.

Air and mercury being in separate compartments assures dependable control of the air in the bolus balloon.

The small size and thick wall of the gravity director head insure against diffusion of a dangerous amount of intestinal gases.

The more tense bolus balloon of smaller air capacity probably affords a stronger stimulus to peristalsis and gives the bowel wall a more firm substance to grip and propel along.

The terminal hole and proximal balloon make possible local barium diagnostic studies, when the tip of the tube meets the obstruction. This type of design also permits the use of air injection to open kinks in the bowel distal to the balloon.

Conclusions

The Wild tube affords more rapid passage and more efficient decompression than has been reported heretofore.

Fluoroscopic guidance, until the tube is beyond the ligament of Treitz, is the most certain means of obtaining dependable treatment.

The air injection technique (500-800 c.c. into stomach) has improved passage across the stomach and has probably aided pyloric passage.

The gastric balloon technique has solved the problem of the markedly compressed stomach.

The tube tip was delivered to the pylorus in ninety-nine of one hundred cases. The intubation was discontinued on one case before the tube had been swallowed.

Redistention above the travelling tube, in the case of adynamia, is treated or prevented by gastric suction through the other nostril.

The tube may be passed the entire distance from nose to ileum during an operation by the combined efforts of anesthetist and surgeon.

The criterion of successful small bowel catheterization must be roentgen evidence that the tip of the tube is in the second portion of the duodenum.

Narcotic sedation prior to intubation very likely interferes with pylorus passage.

Mechanical obstruction at the pylorus, and a post-vagotony decompensated stomach are the only consistent causes of failure to pass the pylorus in this series.

Decompression in inhibitory ileus and postoperative distention is considerably slower than in primary obstructions but there are patients in this series with severe and definite adynamia who were rapidly intubated.

Patients with a gastroenteric stoma have about the same pass rate and final success as those with a pylorus.

In acute obstructions, of all types, 44 per cent of the cases can be intubated in 30 minutes or less. Therefore an attempt at intubation may well be worth while even in patients who are to be operated on at once.

In this series 73 per cent of those with primary obstructions either had no operation or were operated upon after hydration and decompression.

A corrected mortality of 7.3 per cent for primary obstructions of all types, and 11.6 per cent for postoperative distention was observed in this group of 100 consecutive intubations.

Discussion by Dr. John J. Wild

Long Intestinal Tube Design

So far no entirely satisfactory long intestinal tube has been produced commercially. In 1942, finding the existing so-called Miller-Abbott tubes unsatisfactory in England, I decided to try to improve them and have been working almost exclusively on the problem since then.

It has not been possible to get satisfactory co-operation from commercial interests, so methods of fabrication in the laboratory of experimental designs of long intestinal tubes have been developed. In this way it has been possible to test designs quickly and efficiently with the result that an almost completely satisfactory clinically tested tube has been developed. This tube, together with a simple technique which has been developed, has resulted in a decided advance in the use of long intestinal tubes in the direction of rapid introduction in practically all types of cases. Ease and simplicity of introduction is increased and worry and detailed nursing care of the patient are reduced.

The present design consists of a nine-foot tube of adequate suction lumen made of a non-irritating plastic material. Freedom from kinking and twisting is assured by adequate thickness of the wall.

The design of the aspiration orifices represents a considerable advance. Such orifices are placed at the tip of the tube, are two in number, and obstruction from twisting or acute bending is prevented by a metal insert held in place by the binding of the intestinal balloon and of the gravity director head.

An inflatable bolus of special design is attached just proximal to the aspiration holes. This bolus is inflated by a separate plastic tube which will ultimately be attached to the main suction tube in such a way as to avoid costly metal connecting pieces.

The bolus has a primary inflation capacity of 5 c.c. and can be increased subsequently to 10 c.c. and then to 20 c.c. after the duodenum has been passed.

The 20 c.c. distention is used for intestinal travel. The balloon is distended spherically under pressure so that a very rigid bolus is formed which makes for easy handling of the tube during operations where it is desired to decompress the distended bowel. Fifty c.c. distention under pressure effectively seals the bowel proximal to the aspiration holes so that radiopaque media can be injected distally into the lumen of the bowel. Air also can be injected distally into the bowel for the purpose of removing kinks due to postoperative adhesions.

The gravity director head is a carefully designed sack of rubber partially filled with 2.5 c.c. of mercury. The head can be introduced easily into the nose without instruments and is of such a shape that it will negotiate the lower end of the stomach and pyloric region. Should the sack distend with gas, the size assumed is not sufficient to cause trouble upon removal. The gravity director head is attached to the tip of the tube and pulls the tube end-

Dr. Wild is Research Fellow, National Institute of Health.

wise behind it so that there are no projecting tips to catch at the lower end of the esophagus or pylorus.

This arrangement of intestinal balloon, aspiration holes and gravity director head from above downwards has been found to be the most expedient way of rapidly transversing the gastrointestinal tract in cases of intestinal distention.

With such a tube design it has been found possible to deliver the tip of the tube to the pylorus in a matter of minutes with the aid of fluoroscopy in all but the very severest grades of distention, which are very rare. Thus a true evaluation of the pylorus as a cause of difficulty can be arrived at. The principle of the technique is to inject sufficient air into the stomach to give the tube tip free access to the pyloric antrum. The injection of air in the severest grades of distention can be carried out only in tubes with terminal holes.

A consideration of the perplexing number of tubes which has been available to the profession commercially will show in the light of the foregoing material that their design leaves much to be desired if the previous mistakes in design of the commercially produced so-called Miller-Abbott tubes are to be avoided.

The So-Called Miller-Abbott Double Lumen Tube (1938).—The double-lumen construction was responsible for the discrediting of the work of Johnston and Abbott in that an adequate suction lumen was not provided. The original investigators used separate inflation and suction tubes so that an adequate suction lumen was provided. Further, costly and inefficient metal connecting pieces are obligatory with this type of construction. The metal connection piece introduces a constriction in the suction line and the two connectors to the balloon and suction lumen give rise to confusion so that irrigation fluid or barium may find their way into the balloon. This may have serious consequences if unrecognized.

The tying-on of the condom-thin balloon is not easy, since no metal insert is provided proximally to prevent occlusion of the inflation lumen if the binding is applied too tightly. Leakage of the balloon may occur if the binding is too loosely applied in an attempt to avoid obstruction of the lumen. The balloon is filled and not distended with air. This makes handling of the tube difficult through the bowel wall at operation.

A terminal metal bucket is provided with multiple perforations to form a strainerlike tip. This projects from the balloon and is liable to get caught at constrictions of the gastrointestinal tract. Also, when in use, it clogs rapidly, leaving the burden of aspiration to the holes situated proximal to the balloon. These proximal holes are small and distributed along the tube axis for some distance, so that maximum suction is obtained only at the most proximal hole. The holes are too small and are unsupported. Since the bowel lining membrane can get sucked into the holes, resistance to travel occurs, and this is probably one of the reasons for failure to decompress true adynamic ileus.

The use of mercury in the balloon of the Miller-Abbott tube was suggested by Dr. Ivar Sivertsen of Minneapolis in 1941. It improves greatly the passage rate of the tube into the duodenum, but the tip may often impede if not completely arrest the tube. Doubling of the tube may also occur. The mercury is inserted after the tube has been passed into the stomach. Thus the valuable aid of the mercury to swallowing is lost. If inserted before passage, the danger of rupture of the thin condom is very real. Having gotten the tube into the bowel, its performance still leaves much to be desired. The rubber is very irritating to the nose. None but the largest size is reasonably efficient relative to the suction lumen and this tube is too large for most noses. The metal connection piece offers further resistance to the intestinal contents.

The Harris Rubber Tube (1945) and Its Plastic Modification by Herrerra et Al.—This is a single-lumen tube having a full size condom attached to the end as with the Miller-Abbott tube. Seventy grams of mercury are used as a bolus. The Harris tube has a totally inadequate suction lumen and is made of rubber. The Herrerra modification provides a much larger and adequate lumen and is made of Koroseal surgical tubing. The size of Koroseal recommended by Herrerra et al is prone to kinking, owing to the thin wall selected. Adequate removal of intestinal contents is provided by a suitably large bore. Herrerra et al also suggested using a double condom to minimize the risk of rupture when passing it into the nose. Inflation of the condom spontaneously in the bowel, due to diffusion of gases, has been reported by Harris as a frequent complication. This can be avoided by flushing out the balloon with carbon dioxide, or, more easily, by the use of Neoprene synthetic rubber. The projecting tip of the tube is liable to get caught up, as with the so-called Miller-Abbott tube.

The Cantor Tube (1946).—This is another single-lumen tube of rubber of adequate lumen with multiple unsupported holes placed axially in groups, with the disadvantages previously described. The gravity director head is unnecessarily large and has a blunt end which does not utilize the properties of the mercury to maximum advantage. Arrest or delay at the lower end of the esophagus or pylorus is not infrequent. It is also more difficult to get into the nose than my original design. Autoinflation in the gut is prevented by using Neoprene rubber which will have to be tested by experience. The tube is rather large for the comfort of the patient and thus causes considerable resistance in the nasal passages. It is doubtful whether the mercury bolus alone is as efficient as a balloon bolus, on the basis of experiments on myself with a number of designs of tube. Other faults can be deduced from the foregoing material.

The Kaslow Tube (1947).—This is useless, since the wall of the suction tube is totally inadequate and adequate suction merely flattens the tube.

The Honor-Smathers Tube.—This is a commercially produced plastic tube of the best design to date. The lumen is adequate, the metal connecting piece is well designed though liable to confusion. There is an inflatable gravity director head which is inflated by means of a very small inflation lumen in the wall of the tube. The plastic is poorly compounded in that it gets stiff quickly on use. The holes are unsupported, making the tube liable to kinking. They are arranged axially along the tube and are thus inefficient for reasons before mentioned. The inflatable gravity director head is unnecessarily large and has the same disadvantages as the Cantor type, with the additional one of obstructing the flow of intestinal contents to the aspiration holes when inflated. The Honor-Smathers tube has not been described in the literature.

I hope that soon it will be possible to get an efficient tube made according to my specifications, which have been arrived at by much work and observation. Further interesting work is in progress towards a simple solution of a difficult problem which will put into the hands of my colleagues the means of truly evaluating the long intestinal tube.

HAMLIN MATTSON, M.D.
Recorder

Bowel Management of the Irritable Colon . . .

"As an aid in reestablishing a normal rhythm, the temporary use of a bland bulk-producer . . . may be beneficial. . . . Patients having irritable colon who believe they are suffering from constipation commonly use high-residue diets, . . . They may not realize that this practice is similar to using irritating cathartics or large enemas and often increases the tendency to constipation by increasing spasm of the colon."*

Metamucil is "a bland bulk-producer" which gently initiates reflex peristalsis and movement of the intestinal contents. The "smoothage" therapy of Metamucil encourages a return of the normal function of the colon without irritating the mucosa.

METAMUCIL®

is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent.

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

The Industrial Physicians and Surgeons of the United States and Canada will hold their 34th annual meeting at Detroit, Michigan, April 2 to 9, 1949, with headquarters at the Book-Cadillac and Statler Hotels. Participating groups are the:

American Conference of Governmental Industrial Hygienists
American Industrial Hygiene Association
American Association of Industrial Dentists
American Association of Industrial Nurses

The week-long program is featured by (1) Surgical Clinics at the Henry Ford and Harper Hospitals, (2) scientific sessions on such timely subjects as the problems created by atomic radiation, cardiovascular diseases among the employed, alcoholism in industry and toxicities of industrial substances such as beryllium, agricultural chemicals and rare metals and (3) special sessions for physicians in steel manufacturing and heavy industry, in rubber, petroleum and chemicals, in coal mining and metal mining.

Other features are the arrangements for plant tours along the assembly lines of the great automobile companies and through the plants of many of Detroit's famous manufactories. All physicians and surgeons, industrial hygienists, industrial nurses and others interested in industrial health are invited to attend.

Hotel reservations should be made with hotels direct.

AMERICAN COLLEGE OF ALLERGISTS

The American College of Allergists will meet at the Palmer House in Chicago, April 14 to 17 inclusive. More than 1,000 physicians from North America and abroad, who are interested in allergy, are expected to attend. All physicians are urged to attend. An interesting program covering a wide range of allergic conditions will be presented.

Reservations should be made directly with the Reservation Manager, Palmer House, Chicago 90, Illinois, giving the time of arrival and departure.

THE INTERNATIONAL ACADEMY OF PROCTOLOGY

The International Academy of Proctology was founded July 6, 1948, for the purpose of advancing the practice and study of diseases of the colon, to stimulate research, to promote the practical application of all recent advances in proctology, to encourage instruction in the specialty and to publish articles on the subject. Those specializing in proctology, or whose interest lies in the field of proctology, are eligible to membership. Specialists in the field, whose outstanding achievements meet the approval of the Committee on Membership, are eligible to membership as Honorary Fellows. Application should be made to Dr. Alfred J. Cantor, 43 Kissena Boulevard, Flushing, Long Island, for charter membership or Fellowship in the Academy.

INTERNATIONAL CONGRESS ON RHEUMATIC DISEASES

An International Congress on Rheumatic Diseases will be held at the Waldorf Astoria Hotel in New York City from May 30 to June 3, 1949. Mornings will be devoted to addresses, and clinics will be held in the afternoon. Some 150 physicians from foreign countries are expecting to attend, and a number of distinguished foreign guests will participate. English, French and Spanish will be the official languages and instantaneous translations of the scientific papers will be made by means of the I.B.M. wireless system. The meeting is open, and the registration fee is $10.00. The Congress office is at 2020 East 93rd Street, Cleveland 6, Ohio.

USPHS EXAMINATION FOR MEDICAL OFFICERS

Competitive examinations for appointment of medical officers in the Regular Corps of the United States Public Health Service will be held May 3, 4, and 5, 1949, in various cities throughout the country, Chicago being the nearest for Minnesota aspirants.

Appointments will be made in the grades of Assistant Surgeon (1st Lieutenant) and Senior Assistant Surgeon (Captain), and are of a permanent nature.

Applicants now serving internships will be allowed to complete them before going into active duty. Examinations will consist of written professional tests, an oral interview, and a physical examination.

Entrance pay for Assistant Surgeons with dependents is $5,011 per annum; for Senior Assistant Surgeons with dependents, $5,689. These figures include the $1,200 annual additional pay received by medical officers, as well as subsistence and rental allowance.

Complete applications must be received by April 4, 1949. Forms may be obtained by writing to Surgeon General, United States Public Health Service, Washington, D. C.

COMMUNITY SEEKS PHYSICIAN

The Methodist church is seeking a physician to locate at Jasper, Arkansas, to serve in Newton County where 10,000 inhabitants are without a doctor. If a doctor can be found, the Methodist church will organize community support for the erection of a clinic with a laboratory and a few beds, and will subsidize the establishment until a practice can be built up. The state will probably supply a nurse. For further information, write Dr. M. O. Williams, Board of Missions and Church Extension, 150 Fifth Avenue, New York 11, N. Y.

COURSE IN CANCER NURSING

A new course in cancer nursing will be offered during the spring quarter by the University of Minnesota's School of Nursing. The course, beginning on March 28, is open only to graduate nurses. Serving on the faculty will be Mrs. Genevieve Seller of the Public

Health Service of the Federal Security Agency, and Helen Hanson, cancer nursing specialist on the University School of Nursing staff.

The course is being offered in answer to the requests of many nurses who wish to assist in the cancer control program. The planning of the curriculum was executed by several co-operating groups: representatives of the State Board of Health, the Minneapolis Department of Health, Twin Cities Public Health Nursing Agencies, the Minnesota League of Nursing Education, and the University Schools of Nursing and Public Health.

ST. LOUIS COUNTY

The St. Louis County Medical Society held its annual meeting in January at the St. Mary's Hospital conference room. Elected as president of the group was Dr. M. H. Tibbetts of Duluth.

CRIPPLED CHILDREN CLINICS

Each year, in spring and fall, the Crippled Children's unit of the State Department of Social Security holds clinics, conducted by an orthopedist and a pediatrician, throughout the state. Practitioners may refer children for examination and advice irrespective of their financial status. The clinics are free and are in the form of case findings and follow-up of former Gillette Hospital patients.

The spring schedule for 1949 is as follows:

St. Cloud	March 19	Technical High	Stearns Benton Sherburne
Faribault	March 26	High School	Rice Goodhue Scott Dakota
Thief River Falls	April 2	High School	Pennington Marshall Red Lake Roseau Kittson
Worthington	April 9	High School	Nobles Jackson Pipestone Cottonwood Murray Rock
Grand Rapids	April 23	Senior High	Itasca Cass
Austin	April 30	Central High School	Mower Freeborn Steele Dodge
Detroit Lakes	May 7	High School	Hubbard Mahnomen Becker Clay
Moose Lake	May 14	High School	Aitkin Cook Carlton Pine Lake
Brainerd	May 21	Franklin Junior High	Crow Wing Wadena Mille Lacs Todd Cass Aitkin
International Falls	June 4	Alexander Bake	Koochiching
Morris	June 11	High School	Stevens, Grant Pope, Traverse, Douglas, Bigstone

NURSING COURSE OPEN TO MEN

In response to the demand for male nurses to assist in the care of male orthopedic, and psychiatric patients, the University of Minnesota School of Nursing is planning to open its basic professional nursing course to men in the coming fall. The University's basic nursing training consists of a five-year program, resulting in a degree. Men admitted to the School of Nursing must have completed college courses in English, the basic biological, physical and social sciences, and the other required general education courses.

HENNEPIN COUNTY SOCIETY

As of this coming October, Dr. Robert F. McGandy will assume the post of president of the Hennepin County Medical Society. The election took place in early February. Other officers elected were: Dr. John H. Moe, first vice president; Dr. Ernest R. Anderson, second vice president; Dr. L. Haynes Fowler, and Dr. Horatio B. Sweetser, Jr., were elected to the board of directors; Dr. Thomas J. Kinsella and Dr. Donald McCarthy, board of censors; Dr. Malcolm B. Hanson and Dr. Robert L. Wilder, board of ethics. To the board of trustees were elected Dr. Arthur C. Kerkhof and Dr. Malcolm C. Pfunder. Delegates to the Minnesota State Medical Association will be Dr. James K. Anderson, Dr. Lawrence R. Boies, Dr. Ralph H. Creighton, and Dr. Willard D. White.

RED RIVER VALLEY SOCIETY

Dr. George Sather of Fosston was elected president of the Red River Valley Medical Society at the Society's annual meeting, which took place in Crookston in January. Other offices filled were as follows: Dr. K. W. Covey of Mahnomen was elected vice president; Dr. R. O. Sather of Crookston, secretary-treasurer, and Dr. Eugene Sorn of Erskine, censor.

The annual banquet was held at the Crookston Hotel preceding the business meeting. Approximately twenty-five physicians were present.

STEARNS-BENTON MEDICAL SOCIETY

At the regular meeting of the Stearns-Benton Medical Society, held in St. Cloud in January, the attending physicians voted in favor of an improved public relations program which has as its purpose informing the public about the issues involved in the problems of medical care and socialized medicine.

Speaking before the group, on the subject of socialized medicine and co-operative medical enterprises, were Dr. L. A. Vernath and Dr. J. P. McDowell. Dr. Gordon Kamman, St. Paul, discussed the role of the general practitioner in alleviating neurotic difficulties in patients. Introduced by Dr. E. J. Smitz of Holdingford was Dr. Mitrofan Smorczok of Poland, who, now that the citizenship clause has been removed as a requirement for the right to practice in Minnesota, intends to acquire the necessary training and establish practice. The meeting was presided over by Dr. L. M. Evans.

WASHINGTON COUNTY MEDICAL SOCIETY

The Washington County Medical Society held its regular monthly meeting February 8, 1949.

The meeting was devoted entirely to the consideration of the proceedings of the Grass Rôôts meeting in St. Louis, and no compliments were showered on the erratic Mr. Ewing. The major part of the evening was devoted to the offerings of the Speakers at the County Officers meeting January 14, and comments thereon. Pamphlets on "Medical Care in the Atomic Age" were distributed to members.

GRANTS FOR RESEARCH IN CARDIOVASCULAR DISEASE

The American Heart Association has announced that applications for fellowships and for research in cardiovascular disease are available. Application blanks may be obtained by addressing Medical Director, American Heart Association, 1775 Broadway, New York 19, New York.

The ultimate aim of the American Heart Association is to develop a continuing program of productive research within the broad field of diseases of the heart and blood vessels.

The recommendations of the Research Policy Committee were published in the *American Heart Journal* (36:463, September, 1948). These policies are subject to modification by the membership of the Scientific Council of the American Heart Association and approval by the Board of Directors.

The research program of the American Heart Association will be closely co-ordinated with that of the National Heart Institute of the National Institutes of Health, U. S. Public Health Service and with the Life Insurance Medical Research Fund.

LOWEST DEATH RATE IN 1948

The lowest death rate in Minnesota's history was recorded in 1948. Based on reports received up to February 1, 1949, the death rate for the preceding year was between 9.4 and 9.5 per 100,000 population. Not since 1921, the last record year, has the death rate been so low as 9.5. In 1947 it was 9.8. Deaths reported from all causes during 1948 numbered 27,689. Births recorded for the same period totaled 72,500. The all-time high was 75,469 births in 1947.

BROOKINGS REPORT AMONG FIRST TO REFUTE EWING

Mrs. Elmer Rusten

"It is apparent that the United States under its voluntary system of medical care has made greater progress in the application of medical and sanitary science than any other country."

This conclusion is one that physicians and others interested in maintaining the present methods of medical care have been voicing ever since the first Wagner-Murray-Dingell bill made its appearance on the legislative scene. But the quotation does not come from a physician, nor from anyone connected with the medical profession. It is point two in the "Conclusions and Recommendations" of *The Issue of Compulsory Health Insurance,* an impartial, factual study made and published by the Brookings Institution at the request of Senator H. Alexander Smith.

Senator Smith, chairman of the Subcommittee on Health of the senate committee on Labor and Public Welfare, asked the Brookings staff to make the survey because of the number and complexity of the health bills being presented in congress.

Findings of the Institution matched the not-always-fact-supported beliefs of those who favor the democratic way of furnishing and obtaining medical care.

When the fact-sifting was over, the Brookings people found themselves committed by logic to the following:

That the draft rejection statistics are "unreliable as a measure of the health of the nation"; that conditions in extremely poor sections of the country could not be helped by subsidies—some form of economic transfusion is needed to cure the basic ills of these communities; that the people who are unable to pay for adequate medical care now would not be able to do so under compulsory health insurance either because "they would lack the means to attain and maintain an insured status."

Brookings experts also warn that governmental regulation and control of medical care would necessarily result in lowered quality of care at an increased cost (in tax dollars); that the government would inevitably come between the doctor and his patient.

They point out that the issue for the large majority of American families is "not whether they can afford medical care but whether they should be compelled by law to pool their risks." By way of explanation, the report adds that this large majority is able to pay for medical care—it is just a question of "giving it a high priority among the several objects of expenditure."

The Brookings report is by no means entirely negative; the researchers do not stop with disapproving the compulsory health insurance plan; they have alternative suggestions for action:

"For the time being the national government and many of the state governments may well devote their resource and energies to: (a) Research and developments in the field of public health; (b) Health education at the school level; (c) Teaching of preventive medicine; (d) Assisting in the acquisition of physical facilities and training of personnel; (e) Providing systematic care for the indigent and medically indigent."

AUXILIARY STRESSES MEDICAL INSURANCE

Need for voluntary prepaid medical and hospital insurance was stressed at a roundtable discussion of the Red River Valley Medical Auxiliary, held January 18 at the home of Mrs. A. R. Reff. Particular attention was given to the plans of Blue Cross and Blue Shield, now in operation.

Mrs. C. L. Oppegaard reported on the Health Day held in Crookston last October 7, and Mrs. C. G. Uhley and Mrs. M. E. Janssen reported on the recent state Tuberculosis Essay contest and judging.

The session was held following a dinner with the Medical society at Hotel Crookston.

PARK REGION GROUP STUDIES TUBERCULOSIS

Mrs. H. B. Thompson

"Tuberculosis, a Problem," a talk by Miss Margaret Breen of the Minnesota Public Health Association, led off discussion at the January 25 meeting of the Park Region Medical Auxiliary at Fergus Falls. Individual members of the organization are assisting the mobile x-ray units in their own communities, it was noted.

Prior to the discussion, the women were entertained at tea by Mrs. Glenn Mouritson.

AUXILIARY SPONSORS TUBERCULOSIS TALKS EIGHTEEN YEARS

Mrs. David Halpern

The Woman's Auxiliary of the Minnesota State Medical Association has concluded its eighteenth year of sponsoring the high school speaking project on tuberculosis with the donation of two trophies and ten medals.

The project was conducted by the Minnesota Public Health Association, in co-operation with radio station WCCO. An estimated 10,000 high school students prepared talks on "What You Can Do About Tuberculosis" during November and December as an educational feature of the Christmas Seal campaign.

Local judges selected three scripts from each school to be submitted for state judging and the scripts were presented locally before the high school assemblies and adult audiences; in some cases they were broadcast on local radio stations.

The state committee of judges chose ten winning scripts, eight from the senior high school division and two from the junior high school division. These ten authors were introduced in interview programs over WCCO December 11 and 18, E. A. Meyerding, M.D., executive secretary of the Minnesota Public Health Association, conducting the interviews. Mrs. H. F. Wahl-

quist, president of the Auxiliary, presented the Senior High School trophy on the final broadcast.

Thomas Wahl of Cathedral High School, St. Cloud, won the senior division trophy for his school, and Bernard T. Johnson of Franklin Junior High School, Brainerd, the junior division.

The complete list of winners is as follows:

Senior High Schools

First Place Plaque Winner: Thomas Wahl, Cathedral High School, St. Cloud.

Second Place: Gertrude Rath, Loretto High School, Caledonia.

Honorable Mention: Ruth Weber, St. Francis High School, Little Falls; Rosemary Mahoney, Good Counsel Academy, Mankato; Janet Jefferson, Monroe High School, St. Paul; Lois Gravos, Central High School, Red Wing; Arlyn Reinhart, New Ulm High School, New Ulm; Nancy Jane Noreus, Cloquet High School, Cloquet; John Smith, Little Falls High School, Little Falls; Eillen Heerdt, Bird Island Public Schools, Bird Island; Lorraine Hoyhtya, New York Mills High School, New York Mills; Marilyn Prozinski, St. Francis High School, Little Falls; Joseph M. Yaeger, Milaca High School, Milaca; Catherine Meyer, Marshall High School, Marshall; Patricia Hoolihan, St. Joseph's Academy, St. Paul; Burton Wyss, Greenway High School, Coleraine; Juliana Welle, St. Francis High School, Melrose; Lois Kruckeberg, Blooming Prairie High School, Blooming Prairie.

Junior High Schools

First Place Trophy Winner: Bernard T. Johnson, Franklin Junior High School, Brainerd.

Second Place: Ray Salo, Washington Junior High School, Duluth.

Honorable Mention: Patricia Faust, St. Francis High School, Little Falls; Andres Gnifkawski, Cathedral High School, St. Cloud; Susan Kjerner, Rochester Junior High School, Rochester; Loralee Lewis, Central High School, Crookston; Barbara Bossue, Franklin Junior High School, Brainerd; Ronald Duthals, Stillwater Junior High School, Stillwater; Delores Boucher, St. Joseph's Academy, Crookston.

NEW OFFICERS FOR SOUTHWEST AUXILIARY

Mrs. W. G. Benjamin of Pipestone is the new president of the Southwestern Minnesota Medical Auxiliary. Other newly elected officers are: Mrs. David Halpern, Brewster, president-elect; Mrs. John O. Lohmann, Pipestone, vice president; Mrs. Gerrit Beckering, Edgerton, secretary-treasurer.

COMMITTEE TO ANSWER NURSING QUESTIONS*

BETTY FOLEY, *Chairman, Enrollment of Student Nurses, Minnesota Nurses Association.*

What is nursing? How do I become a nurse? How often can I get home? What kind of nursing will I do when I graduate?

These are the questions most frequently asked by the high school student who is trying to make a vocational choice. The Minnesota Nurses Association, realizing high school students' and graduates' need for information, formed a committee on Enrollment of Student Nurses to inform the public about the nursing profession and to

*This report was prepared by Miss Foley at the request of Mrs. Bernard O'Reilley, Emergency Nursing Chairman.

assist the prospective student in preparing herself for her education.

Unfortunately the "nurse in white" dream of many a person melts with the knowledge of school and professional qualifications for nursing: A girl or boy must be a graduate of an accredited high school, must be between the ages of eighteen and thirty-five, in good health, with personal characteristics favorable to nursing and a number of special aptitudes.

Before a student enters school, he or she takes a standardized test. Admission records are studied, a personal interview held and, finally, the candidate's abilities, capacities and character traits are summarized. The school then makes a decision, guiding those suitable into nursing and suggesting other vocations to those who do not seem fitted for the nursing profession.

Once accepted, the student must choose again because there are four types of schools: the school of practical nursing; the three-year curriculum leading to a certificate of nursing and registration; the four-year curriculum leading to a bachelor of arts or bachelor of science degree; and the five-year curriculum which results in the degree of bachelor of science in nursing education or public health nursing. Each type of education prepares the person for some specific position: bedside nurse, hospital nurse, supervisor, army or navy nurse, research nurse, instructor, administrator—even housewife.

More specific information about nurses and nursing may be secured from local hospitals or the Minnesota Nurses Association, 2395 University Avenue, Room 310, Saint Paul, 4.

AUXILIARIES LAUDED IN HEALTH JOURNAL

Minnesota's Health, published by the Minnesota Department of Health, observed in its January issue that medical auxiliaries of the state were co-operating in the educational and fund-raising campaign of the American Heart Association.

Auxiliaries noted specifically were: East Central and Southwestern Minnesota, Hennepin, Mower, Nicollet-Le Sueur, Ramsey, St. Louis, Stearns-Benton, Olmsted-Houston-Fillmore-Dodge and Washington counties.

NEW MSMA PRESIDENT GREETS AUXILIARY

Ernest M. Hammes, M.D.

One of the most important heritages of any president of the Minnesota State Medical Association is the knowledge that during his term of office he will have the advice and co-operation of the Woman's Auxiliary.

I don't think that there has ever been a time when the Auxiliary was thought of as "just another women's club"; from its beginning the association's better half proved itself to be a courageous, forward looking, industrious group of women. And we of the association have constantly before us new examples of the Auxiliary's progressive character — Health Days, public speaking, campaigns for various medically connected organizations, public relations activities stemming from conferences like the PR Workshop last September.

Perhaps we don't express our admiration often enough, so may I take this opportunity to extend to you the grateful appreciation of the Minnesota State Medical Association and my personal thanks for the work you have done and the work which we expect of you this year, as scientific medicine confronts the threat of increasingly questionable legislation.

One thing should be strongly emphasized. Streptomycin is not an overnight cure-all for tuberculosis. Like other valuable drugs, such as penicillin and sulfonamides, it has its assets, limitations and liabilities. It must not be considered as a substitute for sanatorium care, rest in bed and other well-established methods of treatment, such as collapse therapy and other surgical procedures.—Karl H. Pfuetze, M.D., *Diseases of Chest,* (Sept.-Oct) 1948.

In Memoriam

WILLIAM J. DAILEY

Dr. W. J. Dailey, for twelve years a practicing physician at Blooming Prairie, Minnesota, died suddenly January 9, 1948, of a cerebral hemorrhage at his home in Oakland, California.

William Dailey was born February 12, 1884, at Hudson, Wisconsin. He attended Hamline Medical School and obtained his medical degree from the University of Minnesota in 1911. After an internship at Ancker Hospital, Saint Paul, he began practice in Blooming Prairie. In 1925 he moved to Oakland, where he has since practiced. Planning to spend his last days in Blooming Prairie, he purchased a home there. He found the climate of Minnesota too vigorous for his impaired health, however, and moved back to Oakland.

On September 30, 1913, Dr. Dailey married Anne Hanchy. She and their two daughters, as well as two brothers and one sister, survive him.

FREDERICK ARTHUR DRAKE

Dr. Frederick A. Drake, a practitioner at Lanesboro, Minnesota, for fifty-one years, passed away January 31, 1949, after an illness of five years.

Dr. Drake was born July 8, 1870, at Rushford, Minnesota, the son of the late Mr. and Mrs. Charles Drake. He obtained his medical degree from the University of Minnesota Medical School in 1896, and interned at St. Joseph's Hospital, Saint Paul.

Beginning practice at Lanesboro in 1898, he became active in the life of the community in a manner that made him an important civic figure. He served as mayor of Lanesboro for many years, was a member of the school board, city health officer, and physician for the Chicago, Milwaukee Railroad.

Dr. Drake married Nellie F. Rafferty of Peterson, Minnesota, on November 22, 1899. He died on March 29, 1948. He is survived by a son, Charles, of Lanesboro, and one brother, Dr. Charles R. Drake, of Minneapolis.

JOHN HENRY WALLINGA

Dr. J. H. Wallinga, of Saint Paul, was killed in an automobile accident on February 8, 1949. His wife and her brother, Mr. E. M. Stern of Fargo, were seriously injured in the accident.

Dr. Wallinga was born in December, 1889, in Hull, Iowa. He graduated from the University of Minnesota Medical School in 1919. He has practiced in Saint Paul since graduation and at one time acted as police surgeon in Saint Paul.

He is survived by his wife and his son, Dr. Jack Wallinga, who recently completed his internship in Cleveland.

Speakers and Entertainers Who Wear Glasses Will Appreciate MAY-O-LITE

Entertainers and speakers find it important to establish a relationship with their audience through eye-contact.

A speaker or entertainer seldom realizes that reflected light upon the surface of his glasses can be a cause of an unresponsive audience. MAY-O-LITE answers this problem.

MAY-O-LITE is a scientific method of cutting down annoying surface reflections upon lenses. With MAY-O-LITE these reflections are reduced up to as much as 95 per cent, eye strain is minimized and lenses become far more resistant to scratches.

Whether or not your patients are public speakers or entertainers, tell them about MAY-O-LITE.

MAY-O-LITE Low Reflection Lens Coating is available through your manufacturing and dispensing optician. Write for a descriptive pamphlet and a treated sample of glass, today.

DEALERS IN DEPENDABLE MERCHANDISE

Dr. Edward Detjen, formerly of Robbinsdale with offices in Minneapolis, has now started practice at the Big Fork Hospital where the need for a local physician has been severe for some time.

* * *

Dr. and Mrs. Wallace Lueck, formerly of Minneapolis, moved recently to 2939 York Avenue in Robbinsdale. Dr. Lueck, however, continues his practice at the Nicollet Clinic.

* * *

Dr. E. E. Wollaeger, Mayo Clinic, attended a meeting during the first week of February in Johnson, Tennessee, where he spoke on "Pancreatitis" to members of the Tri-County Medical Society and the staff of the Veterans Administration Hospital.

* * *

Dr. J. Emery Frank, formerly of Marshall, has established a new practice in Salt Lake City, Utah. Before leaving Marshall, Dr. Frank turned his patient files over to Dr. Kenneth Peterson.

* * *

Dr. Benjamin Spock, chief psychiatrist of the Rochester Child Health Project, spoke at a public meeting sponsored by the Minnesota Mental Hygiene Society at the University of Minnesota in January. His subject was "A Pediatrician Looks at Mental Health."

* * *

The Sioux Valley Medical Association announced last month that over 200 physicians from Minnesota, Iowa, Nebraska and South Dakota attended the annual convention which was held at Sioux Falls.

Dr. L. G. Idstrom spoke recently on the topic, "X-Ray Physics and Electrical Circuits of an X-Ray Machine" at a meeting of the Arrowhead Society of X-Ray Technicians. Dr. Idstrom is an associate radiologist at the Swedish Hospital in Minneapolis.

* * *

Dr. O. M. Heidberg, of Worthington, delivered a talk on "Group Practice of Medicine," in February, to a senior group of medical students at the University of Minnesota. His talk marked the third year Dr. Heidberg has spoken for the senior class. He was teaching fellow at the University's department of internal medicine from 1936 to 1938.

* * *

Dr. F. W. Walter, of International Falls, spoke at a meeting of the Border Registered Nurses Club in February. His discussion centered about the causes and effects of leprosy. Dr. Walter accompanied his talk with slides of Korean lepers which he took while serving in the Pacific theatre of war.

* * *

An innovation in the method of treating thigh bone fracture has been developed by Dr. John H. Moe and Dr. Harry B. Hall, both of Minneapolis. The two physicians presented a paper on their work before the sixteenth annual meeting of the American Academy of Orthopaedic Surgeons which was held in Chicago late in January.

* * *

On January 27, Dr. and Mrs. H. H. Young of Rochester left on a sixteen-day cruise of the Caribbean. Sailing on the flagship *America,* the Youngs left from New

York, beginning a trip which carried them through San Jann, Puerto Rico, Trinidad; and, return, via Havana, Cuba.

* * *

Dr. Miland E. Knapp, associate professor of physical medicine at the University of Minnesota, and Nellie Gorgas, superintendent of St. Barnabas Hospital, spoke last month in Minneapolis at a meeting of Crippled Child Relief Inc.

* * *

Giving a report of his experiences as medical observer of the Bikini Atom Bomb experiment, Dr. Asher White of Minneapolis spoke recently at the Messiah Lutheran Church to members of the men's clubs of both the Messiah Lutheran and Our Saviour's Lutheran Churches.

* * *

Dr. A. B. Rosenfield, acting Medical Director of Health Unit Six, delivered a talk on Child Health at the Coon Rapids Farm Bureau Meeting on January 20. Dr. Rosenfield accompanied his talk with movies on child diseases.

* * *

Dr. C. F. Code of Rochester attended the Conference of Metabolic Interrelations, sponsored by the Josiah Macy, Jr. Foundation of New York City, recently. Dr. Code delivered a paper on "Determination of Gastric Secretory Inhibitor Activity and Its Occurence in Gastric Juice and Gastric Mucin."

* * *

Dr. H. L. Williams, Mayo Clinic, attended the Section of Otolaryngology and Opthalmology of the Houston Academy of Medicine in Texas early in February, speaking on "Changing Concepts of the Treatment of Sinusitis," and "Diagnosis and Treatment of Ménière's Disease."

* * *

In the third week of January, Dr. N. W. Barker of Rochester attended a meeting of the Josiah Macy, Jr. Foundation Conference on "Blood Clotting and Allied Problems" in New York City. His paper, "Surface Effects on Coagulation," was presented before the Conference.

* * *

In response to an invitation extended by the Egyptian government, Dr. G. J. Thompson, head of the section in urology, Mayo Clinic, left in January to give a short course of instruction at the University of Cairo. Dr. Thompson was accompanied by his wife and young son on the trip to Egypt.

* * *

Dr. Harry W. Christianson and Dr. Robert J. Jenner have announced their recent partnership. They have taken over the practice of the late Dr. Harry F. Bayard and are located at 420 Medical Arts Building, Minneapolis. Their practice is limited to surgery and diseases of the intestinal tract.

* * *

Dr. O. L. Pearson of Warroad had an unusual call last month when he was asked to help an injured workman in Northwest Angle. Dr. Pearson was flown to the scene of the accident where he treated the workman, before both patient and physician were flown back to Warroad.

* * *

Secretary of Defense, James E. Forrestal has recently appointed Dr. F. J. Braceland of Rochester as a member of the Armed Forces Medical Advisory Committee, whose principal function at the present time is the co-ordination and unification of the medical services in the armed forces.

* * *

Dr. O. B. Mork, Jr., of Worthington, delivered a talk in Pipestone on February 22 which launched the Second Southwestern Minnesota Health Day. Dr. Mork, Medical Director of State Health Department District Five, reviewed in his morning "keynote" talk the health progress which has been made during the past year.

* * *

Dr. George Haggard of Minneapolis celebrated his ninety-third birthday on January 18. Though Dr. Haggard finds it necessary to reduce his medical activities more and more, he has not relinquished his practice entirely; thereby gaining the title of Minnesota's oldest practicing physician.

* * *

Attending a meeting of the Chicago Neurological Society were Drs. W. M. Craig, J. W. Kernohan, and H. W. Woltman of Rochester. Each spoke: Dr. Craig, on the "Surgery of Intraspinal Lesions"; Dr. Kernohan, on "The Pathology of Spinal Cord Tumors"; and Dr. Woltman, on "Intramedullary Tumors of the Spinal Cord and Gliomas of the Intradural Filum Terminale."

Sixty-three public health centers have been approved to date for Federal aid under the National Health Program. Total Federal funds of more than $107,000,000 have been allocated to hospital construction projects under this program, to cover the cost of a total of 645 hospital and health facilities.

* * *

Dr. Ralph L. Estrem of Fergus Falls received a leave of absence from the Estrem Clinic recently in order to augment his training in x-ray and internal medicine. Dr. Estrem and his family will make their residence in Minneapolis during the period required for his postgraduate studies.

* * *

The first memorial lecture in honor of the late Dr. Luthard M. Bergh of Montevideo was presented on February 16 at the University of Minnesota by Dr. A. C. Ivy, physiologist of the University of Illinois. The talk, delivered at the Minnesota Museum of Natural History, was sponsored by the Minnesota Medical Foundation.

* * *

Dr. Katherine A. Nye was honored earlier this year when the Ramsey County Medical Society presented her with an award designating her the outstanding practitioner of Ramsey County. Dr. Nye and her sister, Dr. Lillian Nye, have maintained practices in this area since their graduation from the Medical School of the University of Minnesota—graduating in 1915 and 1921, respectively.

At the Mid-West Cancer Conference, which was held in Wichita, Kansas, during the third week of January, two papers were presented by Dr. Talbert Cooper of Rochester. His subjects were: "Diagnosis of the Leukemias and the Lymphoblastoma Group" and "Recent Advances in the Treatment of the Leukemias and the Lymphoblastoma Group."

* * *

Dr. W. F. Kvale of Rochester presented a talk in January on the "Diagnosis and Treatment of Occlusive Arterial Disease" before the Sioux Valley Medical Association in South Dakota. Accompanying him on the trip was Dr. R. L. Parker who also presented a paper: "Management of Acute Myocardial Infarction with Emphasis on Anticoagulant Therapy."

* * *

Dr. J. Edwards of Rochester attended two meetings in Washington, D. C., during January: The Army Institute of Pathology and the Committee of the American Heart Association, for the establishment of a registry on cardiovascular pathology. He delivered a talk before the former group, speaking on "Pathology of Coarctation of the Aorta."

* * *

Of sixty-four medical men now employed as teachers at the Army Medical Department Research and Graduate School in Washington, D. C., three are from Rochester, Minnesota. They are: Drs. Wallace E. Herrell, Jesse L. Bollman, and K. G. Wakim. The course, open

only to medical men, is teaching the basic sciences on the graduate level for physicians in training in the Army Medical Department Professional Training Program.

* * *

Dr. James C. Crabtree has moved from Princeton, Minnesota, to Bessemer, Alabama, where he will be associated with two other physicians on the staff of the United States Pipe and Foundry Company. There will be adequate opportunity also for him to maintain a private practice. Dr. Crabtree was associated with Dr. A. T. Kapsner at the Princeton Clinic.

* * *

Dr. Corwin Hinshaw is leaving his position on the Mayo Clinic staff to become clinical professor of medicine at Stanford University, Palo Alto, California, as of April 1, 1949. Dr. Hinshaw visited Los Angeles in January in order to present lectures for a course on pulmonary disease, sponsored by the American Trudeau Society.

* * *

It was announced the first of the year that Dr. J. A. Sanford, in partnership with Dr. Norton Rogin, had relinquished practice in Farmington, continuing solely at the Orchard Lake office—both of which establishments Drs. Rogin and Sanford run in association. They will continue to operate and care for their patients together at Sanford Hospital, as in the past.

* * *

Dr. R. W. Keyes, originally of Pipestone, moved his residence and practice to Hastings in January in association with Dr. R. C. Radabaugh. Dr. Keyes, a graduate of the University of Minnesota Medical School in 1946, interned at the Mercy Hospital in Chicago before completing his residency at the Mercy Hospital in Janesville.

* * *

Dr. Robert Semsch of Minneapolis was named county physician of Hennepin County in January to replace Dr. Charlotte Morrison whose term, held since 1940, expired on January 1. Dr. Semsch's duties will include medical services to the Home School for Girls, the Glen Lake Home School for Boys, and the Vince Day Center for Children.

* * *

Dr. Randolph Lee Clark, Jr., former Mayo Foundation Fellow in Surgery, was appointed recently as dean of the University of Texas Postgraduate School of Medicine in Houston. Dr. Clark, associated with the Foundation from 1935 to 1938, has in recent years been director of the M. D. Anderson Hospital for Cancer Research in Houston.

* * *

Dr. C. M. Niles, practicing physician in Forest Lake, was the object of a freak accident late last month which cost him a broken hip. While asleep in his home, a large truck crashed into Dr. Niles' home, throwing him some several feet into his yard. Aided by Dr. J. A. Poirier, Dr. Niles administered self-treatment, whereupon he was rushed to St. Barnabas Hospital, Minneapolis.

* * *

Dr. Robert Hunt of Fairmont was named chairman of the Martin County Nursing Advisory Board of 1949 at the regular meeting of the board on February 7. Elected as board members were: Dr. A. H. Schmidt of Triumph, and Dr. A. C. Burmeister of Fairmont. They were elected to fill the vacancies left by Dr. John Campbell and Dr. Robert Bailey.

* * *

Grants of $209,838 by the National Cancer Institute to support laboratory and clinical research in cancer were announced in January by Oscar R. Ewing, Federal Security Administrator. Grants of $1,319,000 for cancer control, as well as research, which were also recommended by the National Advisory Cancer Council, were offered in December.

* * *

The American Hearing Society has announced that a scholarship of $100, known as the Coralie Noyes Kenfield Scholarship for Teachers Training Courses for Teachers of Hard-of-Hearing Adults, is available for a prospective hard-of-hearing teacher. Applications should be submitted before March 1, 1950, to the Society at 17 14th Street N. W., Washington 5, D. C.

* * *

Drs. C. F. Lake and C. W. Rucker attended a meeting of the Sioux Valley Eye, Ear, Nose and Throat Academy late in January; the former presenting a paper: "Mucoceles and Pyoceles of the Frontal and Ethmoid Paranasal Sinuses"; the latter giving a talk: "Some Affections of the Optic Nerves." Dr. Lake also spoke at the Sioux Valley Medical Association. His paper was entitled "Diagnosis of Chronic Sinusitis."

Among the thirty-eight Minnesota physicians attending the Center for Continuation Study, at the University of Minnesota, course for specialists in ophthalmology were the following: Dr. Joseph Benedict Gaida, St. Cloud; Dr. Reginald Salter of Minneapolis; Dr. Ervin Thaddeus Rechlitz of Albert Lea; Drs. George L. Loomis and F. J. Vollmer, Winona; Dr. M. E. Mosby of the Long Prairie Clinic; Dr. T. R. Fritsche of New Ulm.

* * *

Late in January it was announced that Dr. M. J. Lester of St. James would begin practice in Madelia in association with Dr. H. E. Coulter. Dr. Lester, a graduate of Macalester College, has attended the University of Louisville in Kentucky, and his internship was completed at the Swedish Hospital in Minneapolis last November. During World War II he served as a pharmacist's mate in the United States Navy.

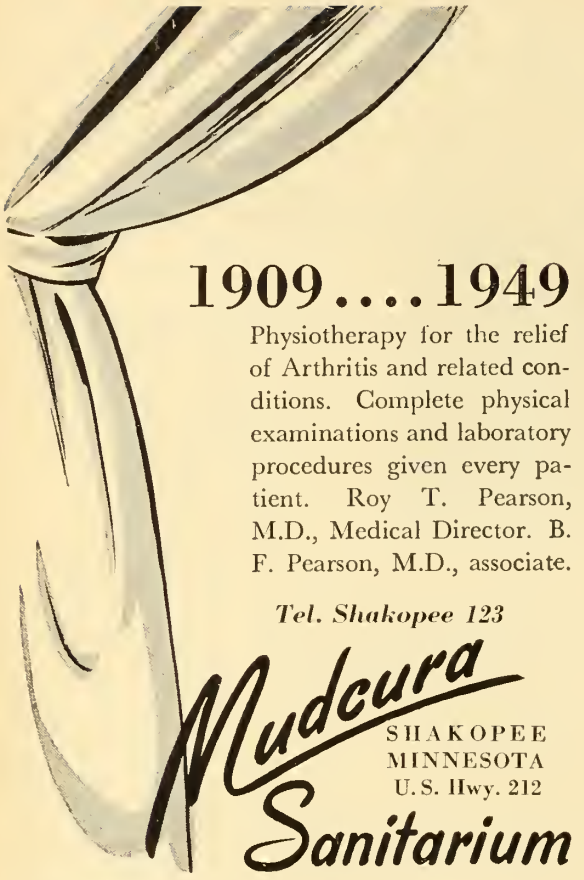
* * *

Elected as a member of the Inter-urban Academy of Medicine of Duluth and Superior late in January was Dr. Ralph Papermaster of Two Harbors. The Academy, one of the oldest of its kind in the United States, has been in existence since 1894. Dr. Peterson, a member of the staff at both St. Luke's and St. Mary's Hospitals, also serves as staff member at the Two Harbors Hospital.

* * *

At the University of Minnesota's Center for Continuation Study, February 17 and 18, classes were held for lay students concerning the latest developments in cancer. Heading the faculty for the school were Dr. Arthur H. Wells of Duluth, president of the Minnesota Division of the American Cancer Society, and Dr. Harold S. Diehl, dean of the Medical School at the University of Minnesota.

* * *



Speaking on "Tuberculosis and Its Control," Dr. Karl Pfuetze, Superintendent of the Mineral Springs Sanatorium at Cannon Falls, recently addressed a public meeting sponsored by the Dakota County Nursing Service jointly with the Lakeville Health Council, at Lakeville. The talk was preliminary to a county-wide Mantoux testing program which will begin this spring.

* * *

Speaking at the thirty-ninth annual dinner of the Jewish Family and Children's Service on January 12 was Dr. Maurice Walsh, psychiatric consultant to the United States Surgeon General. Dr. Walsh spoke on "Family Problems and Their Effect on the Children in the Home." Known for founding the counseling clinic in Rochester, Dr. Walsh has been a member of the Mayo staff since 1934.

* * *

Attending the courses at the Center for Continuation Study at the University of Minnesota on Heart Disease, which were offered during February, were Dr. and Mrs. A. R. Reff of Crookston. Lecturing at the Center were Dr. Paul F. Dwan of Minneapolis, president of the Minnesota Heart Association, and Dr. George Aagaard, acting director of Postgraduate Medical Education at the University. Discussion centered around the use of dicumarol and heparin drugs.

The United Public Health League, organized among a group of northwestern states several years ago, has been maintaining a Washington office for the observation of political trends of medical interest and the dissemination of news in its Washington Letter. With the expansion of the AMA office in Washington, the need for this additional office ceases, and it has been closed. The organization will continue to operate, however.

* * *

From Arlington, Virginia, has come the announcement that Dr. Alvin B. C. Knudson, Washington, D. C., was recently appointed Chief of the Physical Medicine Rehabilitation Division, Department of Medicine and Surgery, Central Office of the Veterans Administration. Dr. Knudson is a graduate of the University of Minnesota Medical School; he later took postgraduate work in Physical Medicine at the Mayo Clinic and the Massachusetts Institute of Technology.

* * *

According to a recent report by Dr. Frank G. Dickinson, director of the Bureau of Medical Economic Research of the AMA, there were some 199,755 living physicians in the United States on June 1, 1948. This is 17 per cent more than the 170,163 physicians shown in the 1940 AMA Directory. The population of the country has increased only 12 per cent since 1940. The physicians in Minnesota number about 4,263, as compared with 30,970 in New York, 16,069 in California and 13,307 in Illinois.

* * *

Dr. H. F. Helmholtz of Rochester spoke before the Northwest Pediatric Society in St. Paul in January, presenting a paper entitled "After-Effects of War on Children in Europe." On the previous day, Dr. Helmholtz addressed the Milwaukee Academy of Medicine, speaking on "A Year in Europe with the United Nations International Children's Emergency Fund." During the first weeks in January, also, Dr. Helmholtz spoke to the Junior Red Cross Leadership Training Institute in Minneapolis on "Health Problems of Children Overseas."

* * *

Dr. Clarke W. Mangun, Jr., a senior assistant surgeon with the Public Health Service, has been assigned to the Minnesota State Health Department to assist in the tuberculosis control work in the Twin Cities. He has had experience in the state health departments in Florida and Kentucky, and recently he received a Master's Degree in public health at Columbia University, New York. His activities here will be directed toward improving the services available to physicians in keeping tuberculosis patients under control.

* * *

It was announced on January 20 that Dr. Manley F. Juergens of Minneapolis had joined the staff of the Johnson-Haberle Clinic in Minneapolis. While with the clinic, Dr. Juergens will specialize in internal medicine and x-ray. Recently Dr. Juergens was associated with Dr. A. E. Walch of Minneapolis, before which he served with the army medical corps for two years. A graduate of the University of Minnesota Medical School in 1945, he served his internship with the Minneapolis General Hospital.

* * *

A new journal, *Fertility and Sterility,* to be sponsored by the American Society for the Study of Sterility and to be published by Paul B. Hoeber, Inc., will appear shortly. Dr. Pendleton Tompkins of San Francisco is the editor and Dr. Abner I. Weisman of New York is managing editor. Twenty distinguished authorities will constitute the advisory board. The journal will be published bi-monthly. Original papers on current topics should be sent to: Dr. P. Tompkins, 450 Sutter Street, San Francisco 8, California.

* * *

Three physicians from Rochester who attended and participated in a meeting of the American Academy of Orthopaedic Surgeons in Chicago were: Dr. M. B. Coventry, who gave a paper entitled "Embryology of the Musculoskeletal System"; Dr. R. K. Ghormley who acted as chairman of the Committee on Graduate Education and Training in Orthopaedic Surgery and the Joint Committee to Study Postgraduate Training; and Dr. H. W. Meyerding who presented an exhibit and delivered an address to the International Society for the Welfare of Cripples.

* * *

On January 19, Dr. W. C. Alvarez of Rochester addressed the Los Angeles County Medical Association

Research Foundation on the subject, "The Importance of Research in Medicine." Later that same week, Dr. Alvarez presented a paper, "The Heredity of Nervous Diseases" to the Western Society for Psychosomatic Medicine in Beverly Hills, California. Speaking also before the Indiana Academy of General Practice later in February, Dr. Alvarez presented to his Indianapolis audience the paper "Puzzling Functional Troubles Found in Practice."

* * *

Two members of the Mayo Clinic have resigned their positions to enter private practice: Dr. P. H. Heersema plans to locate in Minneapolis; Dr. M. P. Kelsey, in Houston, Texas.

Dr. Heersema entered the Mayo Foundation in 1937, being appointed to the staff later in 1939. A consultant in a section on neurology, he was also an instructor in neurology and psychiatry.

Dr. Kelsey was appointed to the staff in 1937. After his service with the Medical Corps during the war, he returned to the Foundation as a consultant in medicine.

* * *

Dr. Vernon A. Doms has recently joined the medical staff of three physicians at the Slayton Clinic, which is to open shortly. Dr. Doms, a native of Woodstock, is the nephew of Dr. H. C. Doms of Slayton. Dr. Doms received his premedical training at Macalester College in St. Paul, taking his medical degree at the University of Minnesota Medical School. His internship was completed while he served with the United States Navy, at the United States Naval Hospital, the Columbus and Providence Hospitals in Seattle, Washington.

Other members of the Slayton Clinic staff are: Drs. O. A. Wiseness, a classmate of Dr. Doms, Dr. Roy Pierson, and Dr. C. Doms.

* * *

On January 16, Mr. and Mrs. A. F. Wellsley, St. Paul, announced the engagement of their daughter, Joyce Mary, to Dr. James P. Lillehei, son of Dr. and Mrs. C. I. Lillehei, Edina. No date, as yet, has been set for the wedding. Both Miss Wellsley and Dr. Lillehei are graduates of the University of Minnesota. She took her Bachelor of Arts degree in speech pathology, while Dr. Lillehei attended the University of Minnesota Medical School. He is, at present, completing his internship at Minneapolis General Hospital before going into residency at the University Hospitals.

* * *

In Easton on February 7, Dr. John J. McGroarty celebrated his sixty-ninth birthday and his fortieth year as a physician. His memory easily encompasses the horse and buggy doctor days; and, further, he is able to recall the time when St. Paul was a town of one house and Minneapolis was a town of three. Educated at secondary schools in the Inver Grove township, Dr. McGroarty attended St. Thomas College and the University of Minnesota Medical School, receiving his degree in 1907. His internship was completed at Ancker Hospital in 1908, from whence he traveled to Easton, establishing his practice there in 1909.

* * *

General physicians from smaller cities and towns throughout Minnesota attended a three-day course in cancer, March 3-5, at the University of Minnesota's Center for Continuation Study in Minneapolis.

The course, covering the latest developments in the diagnosis and treatment of cancer, was offered by the University with the co-operation of the Minnesota State Medical Association, the Minnesota division of the American Cancer Society and the State Department of Health.

Speakers included Dr. Ira T. Nathanson, member of the Harvard Cancer Commission and assistant professor of surgery in the Harvard Medical School; Dr. David P. Anderson of the Austin Clinic at Austin, Minnesota; Dr. John R. McDonald, associate professor of pathology with the University's Mayo Foundation in Rochester, and other specialists in cancer from the University's medical faculty.

* * *

Dr. F. A. Figi of Rochester gave three papers during the month of February: two, "Benign Tumors of the Nose and Throat" and "Malignant Tumors of the Nose and Accessory Sinuses," were given before the Memphis Society of Opthalmology and Otolaryngology. The other, delivered before the Mid-South Postgraduate Medical Assembly, was entitled "Malignant Tumors of the Pharynx and Larynx." Both meetings took place in Memphis, Tennessee.

Dr. Figi assumed his duties as President of the Ameri-

Two special medical lectures, open to the public, were presented March 2 and 3 at the University of Minnesota.

Wednesday, March 2, Dr. E. T. Bell, professor of pathology at the University, spoke on the "Pathology of Diabetes" in the auditorium of the Minnesota Museum of Natural History. Dr. Bell's talk was delivered under the Dr. Clarence M. Jackson lectureship, established as a memorial to the late University anatomist.

Dr. Ira T. Nathanson of Boston, gave the George Chase Christian Lecture on March 3 in the medical sciences amphitheater at the University. Dr. Nathanson spoke on "Hormonal Alteration of Advanced Cancer of the Breast." In addition to his work at Harvard, Dr. Nathanson is associated with the Massachusetts General Hospital, Pondville Hospital and the Huntington Memorial Laboratories.

* * *

In observance of University of Minnesota Week (February 14-21), the University's 98th birthday, many Minnesota physicians co-operated in a special convocation at Northrop Auditorium, held in recognition of the work that has been done at the University's Medical School and through the University's medical facilities. At the convocation, the physicians of the University paid tribute to Mrs. George Chase Christian, who has been singularly instrumental, by her generosity, in the development of cancer facilities there. Speaking in honor of Mrs. Christian were: Dr. Maurice B. Visscher, head of the the department of physiology; Dr. John J. Bittner, holder of the George Chase Christian professorship for the last six years; Dr. Owen H. Wangensteen, chairman of the department of surgery; Dr. Karl W. Stenstrom, professor of biophysics; Dr. John L. McKelvey, head of gynecology; Dr. Ray M. Amberg, director of hospitals, and Dr. Harold S. Diehl, dean of the University's Medical School. Dr. Diehl expressed the gratitude of the patients and physicians who have benefited from the help offered by Mrs. Christian, presenting her with a "Builder of the Name" award, an award which has been conferred on but two persons previously.

HOSPITAL NEWS

According to a recent announcement of the Minnesota Hospital Association, salaries of hospital employes increased 10 per cent in 1948 over 1947. The average starting salary of general duty nurses is $204 per month, an increase of $49 over 1945 and $17 over the 1947 average. Clerks receive an average of $140; and practical nurses, $145, as compared with $132 for 1947. Salaries and employe maintenance service constitute over half the total hospital expenditures.

* * *

As of February first, the charges for services at Ancker Hospital in St. Paul went up "as an effect of the rising cost of hospital maintenance and operation," the welfare board announced. Ambulance charges and operating room fees also rose, the price of rooms on the tuberculosis ward, however, remaining the same. The general rate of advance is $1.00 a day for rooms; $6.50 a day for rooms in contagion sections one and two; $7.50 a day for double bedrooms up to ward beds in contagion sections three and four; and $8.50 per day for single rooms in the same sections. The rates for the operating room range now from $10.00 to $35.00, and the new ambulance charge is $10.00 instead of $5.00.

Dr. Deane W. Benton, formerly of Long Beach, California, has joined the staff of the Worthington Clinic Hospital as general practitioner. Previous to his nine months' residence in California, Dr. Benton practiced in New Ulm. Before that, he served with the armed forces. Dr. Benton and his family have established their new residence at 203 West Ninth Avenue in Worthington.

Wells, chief of laboratories; Dr. F. C. Jacobson, anesthesiology.

Dr. George A. Young, Jr., professor of medicine and psychodynamics at the University of Nebraska, delivered the principal talk at the annual staff meeting.

* * *

The annual staff meeting of St. Mary's Hospital, Duluth, was held February 3, Dr. C. O. Kohlbry, chief of staff, presiding. Following the election of officers and the administrator's report on hospital activities, Dr. John Hirschboeck, dean of the Marquette University Medical School in Milwaukee, spoke on "Present Trends in Medical Education."

* * *

Dr. G. E. Cardle of Brainerd has been elected chief of staff at St. John's Hospital, it was announced in January. Dr. Cardle, succeeding Dr. W. E. Fitzsimons, will hold office through 1949.

The annual banquet, which was held January 14, also marked the election of Dr. A. M. Mulligan as chief of staff to succeed Dr. Cardle; and Dr. J. H. Bebder was elected secretary-treasurer to succeed Dr. Mulligan. Dr. W. W. Will, Bertha, and Dr. E. J. Simons, Swanville, spoke on socialized medicine.

* * *

Dr. Karl Johnson has been elected chief of staff at Miller Hospital, Duluth, for the coming year, succeeding Dr. Keith Fawcett. Also named as officers were: Dr. Miriam Fredricks, vice chief of staff, and Dr. Earl Barrett, secretary. Elected as members of the Executive Committee were Dr. Fawcett and Dr. Henry Jeronimus. Dr. Mario Fischer was elected ex-officio member.

Lecturing on Russia's "Aims and Dreams" was Dr. R. J. Peiper of the Duluth Branch of the University of Minnesota.

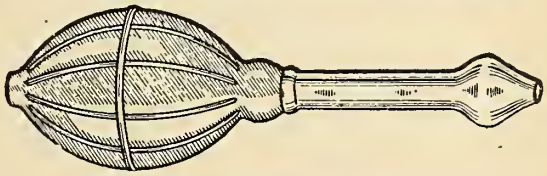
* * *

Elected as chief of staff of the Eitel Hospital recently was Dr. James Blake of Hopkins who succeeds Dr. Wallace Nelson of Minneapolis. Dr. Alton C. Olson, Minneapolis, was elected as assistant chief of staff, succeeding Dr. Alfred Baker. Re-elected as secretary was Dr. Melvin B. Sinyken.

* * *

At the annual staff meeting of the Loretto Hospital, New Ulm, Dr. O. J. Seifert was elected chief of staff. The same honor was bestowed on Dr. Carl J. Fritsche at the Union Hospital annual staff meeting in the same locale.

Receiving secondary posts at Loretto Hospital were: Dr. Wm. A. Black, vice president, and Dr. Albert Fritsche, secretary. Comparable posts at the Union Hospital were accepted by Dr. Theodore R. Fritsche and Dr. F. H. Dubbe, respectively.



* * *

Named as chief of staff at St. Barnabas Hospital, Minneapolis, on February 8 was Dr. Clarence E. Arlander of Minneapolis who has served with the staff since 1936. Dr. Arthur C. Kerkof was elected vice chairman; Dr. Edgar A. Webb, secretary. Dr. Owen F. Robbins, the retiring chairman, will retain his duties as a member of the Executive Committee.

* * *

St. Mary's Hospital in Detroit Lakes, a hospital of sixty beds and fifteen bassinets, was approved during the week of February 3 by the American College of Surgeons. One of nearly 80 per cent of American hospitals to be approved, St. Mary's has been praised for her efficiency and progress in organization and control. Notable among the hospital's accomplishments have been the improvement of working conditions and the reduction of the hospital death rate from approximately 50 per cent down to 3 or 4 per cent at the present time.

P.O. Box 501, St. Paul, Minn.

At the annual meeting of the Red Wing City Hospital, it was proposed that a project of unity be undertaken between the City Hospital and St. John's Hospital, which is situated in Red Wing also. Most local doctors work in both hospitals; thus, it was asserted, a sharing of skilled hospital specialists by the two institutions would greatly facilitate the service to the public.

As regular business of the meeting, the election of staff officers was held. Dr. R. V. Sherman was elected president of the medical staff. He holds the position of secretary at St. John's Hospital also. Elected as vice president was Dr. L. A. Steffens; as secretary, Dr. J. F. Brusegard; and as members of the Executive Committee, Drs. R. B. Braves, R. F. Hedin, and W. W. Liffring.

* * *

Miller Hospital in St. Paul has accepted its first woman intern—Dr. Regine Arnow, a graduate of the University of Minnesota Medical School last June. Dr. Arnow plans to be married shortly to John T. Hoag, a graduate of the University of Michigan Law School, following which she hopes to enter the Children's Hospital in Detroit to serve her residency.

* * *

The Children's Hospital in St. Paul marked its twenty-fifth anniversary early this year. The hospital, now affiliated with the Graduate School of the University of Minnesota, a handsome modern building, began its life in a comparatively unattractive manner. Dr. Walter Ramsey, medical director, saw the need many years ago for an institution which could care for the Northwest's tuberculous children. He had seen such an institution successfully and beneficially operated in Switzerland, and was determined, thereby, to serve the same need here. The financial problem was alleviated but slightly, however, by an unconvinced St. Paul. In 1924, Dr. Ramsey opened a fifteen-bed hospital in an old frame house, paying for the enterprise with funds donated by the few persons who had faith in the project. It was merely a matter of months before the idea proved itself to be a good one. Consequently, in 1927 the present building was constructed. In 1944 another wing was added; and this hospital has the present distinction of being the only one in the Northwest to care for children's diseases from birth to adolescence.

* * *

Dr. John Hirschboeck, dean of Marquette University Medical School, spoke last month at the annual staff meeting of St. Mary's Hospital, Duluth, to the effect that medical schools are carrying the burden of an enlarged enrollment which will not be relieved until the G.I. physicians are graduated and the regular rate of trainees is re-established. He stressed also that the need for medical men necessitated such overcrowding.

Election of officers resulted as follows: Named as chief of staff was Dr. M. A. Nicholson, succeeding Dr. C. O. Kohlbry. Dr. R. P. Buckley was elected chief of staff-elect, and Dr. R. H. La Bree, secretary. Dr. A. J. Spang was named chief of surgery; Dr. R. E. Nutting, pediatrics; Dr. E. L. Touhy, laboratories; Dr. C. W. Taylor, communicable diseases; Dr. Archie Olson, eye, ear, nose and throat; Dr. P. G. Bowman, medicine; Dr. A. O. Swensen, obstetrics; Dr. F. H. Elias, orthopedics; Dr. O. E. Sarff, urology; and Dr. F. T. Becker, dermatology.

* * *

The new hospital at Ely, Minnesota, is rather unique in that its past includes thirty-four years of serving as a school building, and, recently, a thorough-going remodeling job was done in large part by volunteer labor on the part of Ely and Winton citizens eager to have a local hospital. The new institution is the materialization of many years of planning and working on the part of Dr. O. E. Snyker of Ely.

It is a forty-bed hospital, equipped with modern facilities, with much of the present equipment a carry-over from the building's old school days: the bookcases are now supply shelves; and much of the furnishing is material which was salvaged from the War Assets Administration. Work which had to be done at cost was paid for, largely, by donations—small and large—made by local citizens, many of whom have been educated in the building.

Dr. Snyker's medical career began at the University of Minnesota Medical School and his medical training was completed at Loyola University in Illinois, where he graduated in 1934. During the last war, Dr. Snyker served as a Flight Surgeon in the European theatre—at which time, he states, the details of his hospital plan were worked out.

AT HOME OR AWAY SPOT TESTS SIMPLIFY URINALYSIS

No Test Tubes • No Measuring • No Boiling

Diabetics welcome "Spot Tests" (ready to use dry reagents), because of the ease and simplicity in using. No test tubes, no boiling, no measuring; just a little powder, a little urine—color reaction occurs at once if sugar or acetone is present.

Galatest... Acetone Test (DENCO)

FOR DETECTION OF SUGAR IN THE URINE

FOR DETECTION OF ACETONE IN THE URINE

SAME SIMPLE TECHNIQUE FOR BOTH

1. A LITTLE POWDER
2. A LITTLE URINE

COLOR REACTION IMMEDIATELY

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The case also contains a medicine dropper and a Galatest color chart. This handy kit or refills of Acetone Test (Denco) and Galatest are obtainable at all prescription pharmacies and surgical supply houses.

Accepted for advertising in the Journal of the A.M.A.

BLUE SHIELD NEWS

Blue Shield Participants Subscribers covered by contracts in effect as of January 31, 1949.....115,968
(Figures used for previous reports were for Blue Shield applications received as of a given date. The present figure reports persons covered by contracts actually in effect.)
Blue Shield cases paid from January 1 to January 31, 1949..1,522
Amount paid on Blue Shield cases from January 1 to January 31, 1949.....$56,561.68

During the past few months the Blue Shield office has received an increasing number of inquiries from its subscribers requesting information on the benefits provided by the Blue Shield contract and the procedure for filing claims for these benefits. The usual tone of such inquiries is that the attending physician has told the patient to call the Blue Shield office for this information. It is realized that the furnishing of such information is partially the responsibility of Blue Shield office personnel and telephone calls emanating from local subscribers are easily and satisfactorily answered.

However, the out-of-town subscribers have rather a different problem in that they either must write to the Blue Shield office for information or obtain it from the local doctor or the doctor's office personnel. If the information obtained from the doctor's office is insufficient, the patient may get the idea that the Blue Shield contract is not particularly valuable; therefore, there is no need for the potential subscriber to join Blue Shield, nor for the present subscriber to continue his Blue Shield contract. It holds true now just as much as it always has in the past that the doctor is a leading citizen in his community and is looked upon as an oracle on all subjects. Few people remember that the doctor is a very busy man and perhaps does not have the time to read every piece of literature coming into his office, including Blue Shield literature.

Recently, on a trip around the state, a few examples of erroneous information were brought out. However, the opportunity to correct this information was welcomed, and it was also a very great pleasure to learn that the greater percentage of the doctors were well informed on the Blue Shield plan.

As a review, the remainder of this article is devoted to the benefits a Blue Shield subscriber receives and also to some pointers on the processing of medical claims.

Medical care, as distinguished from surgery or maternity care, is provided only if the patient is hospitalized to receive this care. Benefits will be allowed up to twenty-one days in any twelve-month period for the treatment of the same condition. No benefits are allowed for medical care in the doctor's office, the clinic, or the patient's home.

Benefits for surgery are provided regardless of where it is performed, the doctor's office, the patient's home, in the hospital out-patient department, or in the hospital. This also holds true in the setting of fractures, the manipulation of dislocations, the application of casts for corrective purposes, any casts applied to a fracture other than the initial one, the suturing of lacerations, debridement of burns, and skin grafts.

Benefits for obstetrical deliveries are allowed either at home or in the hospital, if the mother is covered by a family Blue Shield contract that has been in effect for ten consecutive months. The Blue Shield allowance of $50.00 for a normal delivery or $100.00 for a cesarean section is only for the delivery and care of the mother and child during the period of confinement. The doctor is at liberty to charge for any prenatal care or postnatal care not covered by this allowance.

Benefits for x-rays up to $15.00 are allowed if taken by or under the supervision of a doctor of medicine who is not compensated by a hospital, and if related to medical, surgical, or obstetrical services covered by the Blue Shield contract.

Payment is made for the administering of anesthesia when given by a doctor of medicine who is other than the surgeon and also is not a salaried hospital employe.

Benefits are provided for tonsillectomies and adenoidectomies performed on minor dependents covered by a

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 S. Honore St., Chicago 12, Ill.

family contract, provided that contract has been in effect for ten consecutive months. Persons covered as a single subscriber do not have a waiting period for this type of surgery since it is possible that a person under nineteen years of age may be employed and thus have his own Blue Shield contract. In these cases there is not the ten-month waiting period requirement for tonsillectomies. Maternity benefits, however, would not be allowed for a single subscriber contract.

A few tips—Blue Shield payments are made every Friday on cases received the previous week. Thus the greater percentage of cases are paid in less than two weeks from the patient's discharge.

When completing the Blue Shield forms, please describe the extent of surgery whether simple or compound, sub-total or total, unilateral or bilateral. This added information helps expedite the case.

If in doubt on a case, send the information to the Blue Shield office, and it will be given consideration with the thought in mind of giving the subscriber the maximum allowance provided by his contract.

Every physician is familiar with the processing of Blue Shield claims for hospitalized patients, the claim being originated in the Blue Shield office and sent to the attending physician for necessary information and return. However, for patients treated outside the hospital, it is the doctor's responsibility to initiate the report and submit it to the Blue Shield office. Every effort is made to keep a supply of these forms in the doctors' offices. An additional supply will be distributed in the very near future.

Recently the question of Blue Shield-Blue Cross providing benefits for diagnostic work performed in the hospital Out-Patient Department has come up. Blue Cross will make no allowance for any hospital expense incurred for diagnostic work on a non-hospitalized patient, nor would any Blue Shield allowance be made for the services of a doctor of medicine in this diagnostic procedure since such services would be classified as medical care rendered to a non-hospitalized patient. However, if the attending physician feels that the patient should be hospitalized for diagnostic study, observation, et cetera, Blue Cross would make its usual allowance for hospital services. The attending physician will also receive Blue Shield benefits for the medical care rendered the patient while hospitalized.

The Blue Shield office will be glad to supply any additional information, and in the event any professional group or county medical society desires a representative of the Blue Shield office at any meeting, such personnel will be readily available.

The strength of Minnesota Medical Service, Inc., lies with its originators, the medical doctors of Minnesota. Their assistance in helping to keep the Blue Shield subscriber fully informed and aware of Blue Shield's value will assure its continued success.

TELEPHONED NARCOTIC ORDERS

(Continued from Page 292)

the person filling such an order, as well as the person issuing it, may be charged with violation of the law.

6. Addiction alone is not recognized as an incurable disease. It is well established that the ordinary case of addiction yields to proper treatment, and that addicts can remain permanently cured when drug taking is stopped and they are otherwise physically restored to health. The so-called reductive ambulatory treatment of addiction has never been sanctioned or approved for the reason that when the addict controls the dosage he will not be benefited or cured.

7. Treatment of addiction, with a view to effecting a cure, which makes no provision for confinement while the drug is being withdrawn, is a failure, except in a relatively small number of cases where the addict is possessed of a much greater degree of will power than that of the ordinary addict.

CANCER FILMS AVAILABLE

The Minnesota Division, American Cancer Society, has announced the purchase of a new film for professional audiences entitled "Cancer . . . The Problem of Early Diagnosis." This film, which is the first in a series, is designed to show that the family physician offers the only immediate hope of reducing the annual toll of more than 180,000 deaths from cancer. Five succeeding films will give more detailed treatment to breast, intra-oral, lung and esophageal, gastro-intestinal, and skin cancer. The series is sponsored jointly by the American Cancer Society and the National Cancer Institute of the U. S. Public Health Service.

A review of this film appeared in the January 20 issue of the *Journal of the American Medical Association,* page 328. It is now available to professional groups on a free loan basis. Bookings will be arranged in their order of receipt in the office of the Minnesota Division, 622 Commerce Building, Saint Paul 1, Minnesota.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

HANDBOOK OF DISEASES OF THE SKIN. Richard L. Sutton, M.D., Emeritus Professor of Dermatology and Syphilology, University of Kansas Medical School, and Richard L. Sutton, Jr., M.D., Associate Professor of Dermatology and Syphilology, University of Kansas Medical School. 749 pages. Illus. Price, $12.50, cloth. St. Louis: C. V. Mosby Co., 1949.

LES MÉTRITES DU COL. Etude Anatomo-Clinique. Nouveaux Traitments. Pierre Durel, Médicin de l'Hôspital Saint-Lazare. Collaborators, Lucien Dutheil, Ancien interne de'Hôspital Saint-Lazare, and Hubert Autrand, Ingénieur, I.E.N. 332 pages. Illus. Price, 650 fr., paper cover. Paris: Masson et cie, Editeurs, 1949.

PREMATURE INFANTS. A Manual for Physicians. Children's Bureau Publication No. 325. Ethel C. Dunham, M.D. 401 pages. Illus. Price, $1.25, paper cover. Washington: Government Printing Office, 1948.

HUMAN RELATIONSHIPS IN PUBLIC HEALTH. A Report of an Institute on Mental Health in Public Health. Geddes Smith. 18 pages. Price, 15c, paper cover. New York: Commonwealth Fund, 1949.

DOCTORS OF INFAMY. The Story of the Nazi medical crimes. Alexander Mitscherlich, M.D., Head of the German Medical Commission to Military Tribunal No. 1, Nuremberg, and Fred Mielke. Translated by Heinz Norden. 172 pages. Illus. Price $3.00, cloth. New York: Henry Schuman, 1949.

CAMPBELL'S OPERATIVE ORTHOPEDICS. Second Edition. J. S. Speed, M.D., editor; Hugh Smith, M.D., associate editor. 2 vols., 1643 pages. Illus. Price $30.00, cloth. St. Louis: C. V. Mosby Co., 1949.

SAFEGUARDING MOTHERHOOD. Sol T. DeLee, M.D. Clinical Instructor of Obstetrics and Gynecology, University of Illinois; Attending Obstetrician at Chicago Maternity Center; Former Associate in Obstetrics and Gynecology, Cook County Hospital. 135 pages. Illus. Price $2.00, cloth. Philadelphia: J. B. Lippincott Co., 1949.

CLINICAL CASE-TAKING. Fourth Edition. George R. Herrmann, M.D., Ph.D., Professor of Medicine, University of Texas. 240 pages. Price, $3.50, cloth. St. Louis: C. V. Mosby Co., 1949.

EMOTIONAL MATURITY; THE DEVELOPMENT AND DYNAMICS OF PERSONALITY. Leon J. Saul, M.A., M.D., Associate Professor of Psychiatry, Temple University School of Medicine; Special Lecturer in Psychiatric Information, Bryn Mawr College. 338 pages. Illus. Price, $5.00. Philadelphia: J. B. Lippincott Co., 1947.

This book of 338 pages, including five pages of references and a nine-page index, deals with the emotional maturity of man. It shows what emotional maturity is, how it is normally achieved, and how its achievement in one respect or another is often prevented or distorted. It shows how important are the early childhood environmental influences, especially in the home. It also shows how the persistence in adult life of immature childish reaction patterns can, under emotional stress, lead to psychoses, neuroses, psychosomatic ailments, and personal or social behavior disorders.

The first half of the book is excellently organized and written. The second half is repetitious in many places, is based too much on military experience during the second world war to be of as great interest to a civilian physician as it might be, and is therefore somewhat of a letdown after having read the first half.

On the whole, the book is well worth reading by any physician who wishes to understand his patients better as persons, rather than just as cases. Also, it is sufficiently understandable for others who deal with people, such as lawyers, ministers, and social workers.

HERBERT BUSHER, M.D.

ANATOMICAL CHARTS. Frank Netter. Summit, New Jersey: Ciba Pharmaceutical Products, 1949. Price $6.50.

Physicians, from time to time, have been receiving anatomical charts from Ciba Pharmaceutical Products, prepared by Dr. Frank Netter. Now 191 of these full-color plates, showing common pathological lesions combined with x-ray pictures and photomicrographs, with explanatory text, have been printed in book form and may be obtained for $6.50, the cost of printing and binding. A check for this amount mailed with order to Ciba Pharmaceutical Products, Inc., Summit, New Jersey, will bring this valuable collection to your desk.

Florence Nightingale Saw the Light

She gave us the light to see the need for a major service in each community. If today you were to take our nursing service from us it would cause a great catastrophe. Nursing is a new profession.

Florence Nightingale started the first nurses' training school less than 100 years ago. Thanks to her for light, vision and inspiration.

Glenwood Hills also saw a light of similar quality 10 years ago when it felt this urgent need for properly trained *psychiatric nurses* to "serve the community, aid the doctor and care for the patient."

Competent, qualified trained nurses are taught by *"competent, qualified* and *trained instructors."*

You doctors can greatly help recruit students by selecting them in your community. Our best graduates come doctor-recommended.

Tuition is free. There is a small charge for matriculation. Help eliminate the nursing shortage by choosing a promising girl, 17 or over, in your community, and sending us her name.

This baby's mother learned about Mead's Oleum Percomorphum from her physician, not from public advertising or displays.
"Servamus Fidem"
HOW much sun does the infant really get?
Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Mead's Oleum Percomorphum is a prophylactic against rickets available 365¼ days in the year, in measurable potency and in controllable dosage. Use the sun, too.
Mead Johnson & Co., Evansville, Ind., U.S.A.

advantage in epilepsy

DILANTIN®

"It has the distinct advantage of being unassociated with mental clouding or drowsiness."* DILANTIN, highly effective in suppressing grand mal seizures, is notably free from hypnotic side-effects thus facilitating the educational, vocational and social rehabilitation of the epileptic patient.

Absence or great diminution in frequency and severity of attacks is achieved with individualized dosage schedules.

ETROIT 32, MICHIGAN

A way to lose money in a hurry

When you are flat on your back with your income cut off and with bills accumulating in increasing amounts as a result of a sickness or accident it's mighty easy to lose money—and in a hurry. In addition to that, the expense of maintaining you and your dependents continues.

The bright thing about the picture is that it's easy to insure your income assuring stability and maintenance of saved capital. It would be smart to insure in an investigated and tested plan, one that is available through your own Society. Apply now!

REFINING THE TOOLS TO DO THE JOB

While medical men are occupied with enlarging their knowledge of disease and treating its manifestations, the makers of ethical drugs concentrate on developing and improving the "tools" to facilitate treatment.

Toward that end, the Smith-Dorsey Company has expanded its research facilities, secured increased research grants and added research personnel.

Our objective — tools worthy of *the finest* workman . . .

Modern ELECTRO-CARDIOGRAPHY

Direct-Recording Cardiotron

Portable, rugged, electrically operated without batteries. Cardiotron is available with or without stand.

The first successful *Direct-Recording* Electrocardiograph...

With more than 1200 now in use throughout the world, the Cardiotron has established the principle of instantaneous recording in general clinical electro-cardiography.

The Cardiotron is fast, accurate and sensitive. It makes an *immediate* black and white cardiogram—on *permanent* chart paper. It is free from skin resistance errors. It reveals more information than any other electrocardiograph instrument.

IMPORTANT: Factory-supervised installation and service are available in most parts of the world. Good deliveries are scheduled. Cardiotron is sensibly priced.

Send for 12-page descriptive booklet

PERTUSSIS VACCINE

COMBINED SQUIBB

THIS EMBLEM is displayed by reliable merchants in your community. Camp Scientific Supports are never sold by door-to-door canvassers. Prices are based on intrinsic value. Regular technical and ethical training of CAMP fitters insures precise and conscientious attention to your recommendations.

CAMP SCIENTIFIC SUPPORTS are prescribed and recommended in many types for prenatal, postnatal, postoperative, pendulous abdomen, visceroptosis, nephroptosis, hernia, orthopedic and other conditions. If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons," it will be sent upon request.

YOUR PATIENT'S MONEY: Economic conditions have shown many swings during the four decades of CAMP history. But Camp prices have always been conscientiously based on intrinsic value. These moderate prices coupled with the functional efficiency and superb quality of Camp Scientific Supports, long recognized by the profession, mean true economy to the patient.

Widely Used..

BECAUSE WIDELY APPLICABLE

Ovaltine in milk, a multiple dietary supplement, is eminently useful in preventing malnutrition referable to nutritionally incomplete diets or to restricted food intake. This flavorsome food drink is widely applicable in dietotherapy of illness and convalescence, and for correcting inadequate nutrient intake in persons of all ages.

1. The protein of this delicious food drink—Ovaltine in milk—is of high biologic value, supplies all the indispensable amino acids required for tissue maintenance and growth and other physiologic needs.

2. Its contained vitamins and minerals provide excellent amounts of vitamins A and D, ascorbic acid, niacin, riboflavin, thiamine, calcium, copper, iron, and phosphorus.

3. Its carbohydrate energy is promptly available for utilization.

4. Its easy digestibility makes for ready absorption of its valuable nutrients.

5. Its delicious flavor, appealing alike to children, adults, and the aged, makes it acceptable even when other foods may be refused.

6. Its multiple nutrients, in kind and amount, make Ovaltine in milk a highly efficient dietary supplement.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Raytheon Microtherm Console Model CMD5 has full floating arm and Directors for treating irregular, local or large areas.

In the model CMD-5 Microtherm, Raytheon offers more than just Federal Communications Commission approval. It brings to the doctor ***microwave radar diathermy***. . . a completely new, scientifically researched postwar tool which greatly expands the science of heat therapy.

Microwave diathermy offers the following features:

- A high degree of absorption.
- Penetrating energy producing deep heating.
- Produces a desirable temperature ratio of fat to vascular tissue.
- Effective production of active hyperemia.
- Desirable relationship between cutaneous and muscle temperature.
- Controlled application over large or small areas.
- Eliminates electrodes, pads and danger of arcs.

ACT NOW to give your patients the benefit of this great advance in diathermy treatment. Ask us to give you a demonstration of the new Raytheon Microtherm or write for MM-449 Catalog.

R.U.Q.

Signs and symptoms referable to the right upper quadrant can be clarified by a cardinal diagnostic step—oral cholecystography with PRIODAX.* With this simple procedure, the diagnosis of chronic gallbladder disease can usually be definitively made or ruled out. Such precision stems from the rapid and almost complete absorption of PRIODAX.

With PRIODAX, the normal gallbladder is clearly and distinctly visualized; whereas nonvisualization or faint visualization almost always indicates cholecystic disease. Due to its optimal radiopacity, gallstones show up well, either as negative shadows (if radiolucent) or as shadows denser than the surrounding PRIODAX (if radiopaque).

PRIODAX

(BRAND OF IODOALPHIONIC ACID—SCHERING)

Patient tolerance to PRIODAX is excellent, untoward reactions such as severe nausea and vomiting are seldom encountered. Loss of the medium is thus avoided and diagnostic accuracy consequently enhanced.

PACKAGING: PRIODAX, beta-(4-hydroxy-3, 5-diiodophenyl)-alpha-phenyl-propionic acid, Tablets are available in envelopes containing six 0.5 Gm. tablets (1 dose); boxes of 1, 5, 25 and 100 envelopes. Hospital Dispensing Package containing 4 rolls of 250 tablets each.

Sick folks sick of soft diets?

-try tempting Swift's Strained Meats!

6 varieties:
Beef, lamb, pork, veal, liver, heart

The foods soft-diet patients have to eat! No wonder they succumb to appetite-apathy.

But many physicians today have discovered there *is* a way to put appetizing, real meat goodness into soft diets. They recommend Swift's Strained Meats. These specially prepared meats retain all their palatability, and a maximum of nutrient value in a form that's highly digestible—easy to eat. To vary patients' menus, Swift's Strained Meats offer six different varieties. Convenient—ready to serve.

Nutritionally, Swift's Strained Meats provide an excellent base for a high-protein, low-residue diet. A rich source of complete, high-quality proteins, they make available simultaneously all known essential amino acids—for optimum protein synthesis. In addition, Swift's Strained Meats supply hemapoeitic iron and goodly amounts of B vitamins. Let Swift's Strained Meats help overcome anorexia in your soft-diet patients!

The makers of Swift's Strained Meats invite you to send for the new physicians' handbook of protein feeding, written by a doctor, "The Importance of Protein Foods in Health and Disease." Send to:

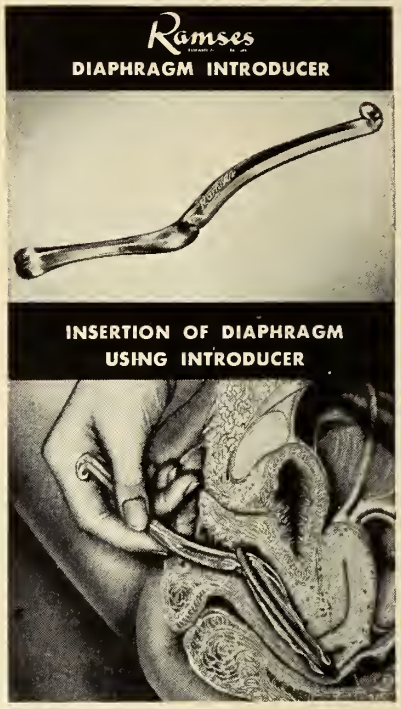
Facts About Conception Control



THE USE OF THE DIAPHRAGM INTRODUCER

Use of a diaphragm introducer is favored by many patients who find manual manipulation objectionable or difficult. It facilitates the insertion and correct placement of the diaphragm, as well as its removal.

The "RAMSES"* Diaphragm Introducer provides the following features:

- Simplicity and convenience in use
- Safety – design minimizes possibility of injury to the cervix or accidental insertion into the urethra
- Smooth surface lessens bacterial proliferation – makes for easy cleaning
- Ease of removal assured by bluntly hooked end

The "RAMSES" Diaphragm Introducer is supplied in the Physician's Prescription Packet No. 501, without charge

Ramses
TRADEMARK REG. U.S. PAT. OFF.

PHYSICIAN'S PRESCRIPTION PACKET NO. 501

A complete unit for conception control. Contains (1) a "RAMSES" Flexible Cushioned Diaphragm of the prescribed size, (2) a "RAMSES" Diaphragm Introducer of corresponding size, and (3) a tube of "RAMSES" Vaginal Jelly† (regular size).

* The word "RAMSES" is a registered trademark of Julius Schmid, Inc.

† Active Ingredients: Dodecaethyleneglycol Monolaurate 5%; Boric Acid 1%; Alcohol 5%.

How mild can a cigarette be?

In a recent coast-to-coast test, hundreds of men and women smoked Camels—and only Camels—for 30 consecutive days. These people smoked on the average of one to two packs a day. Each week, during the entire test period, throat specialists examined these Camel smokers. A total of 2470 careful examinations were made. The doctors who made the throat examinations of these Camel smokers reported:

"NOT ONE SINGLE CASE OF THROAT IRRITATION due to smoking CAMELS!"

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel!

Money-Back Guarantee!

Smoke Camels and test them in your own "T-Zone"—T for taste, T for throat. If, at any time, you are not convinced that Camels are the mildest cigarette you have ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. *(Signed)* R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina.

Show How = Know How

Knowing that the success of her business career depends to a major extent on the satisfaction her patrons derive from their Luzier preparations, your Cosmetic Consultant is vitally concerned not only that the preparations are suited in every respect to your requirements and preferences but, just as important, that you thoroughly understand the sequence and manner of applying them to obtain the best results.

The Luzier Application Chart is designed for her to use in showing you how we recommend that our preparations be applied. This chart provides space for an outline of your service with suggestions based on your particular requirements.

CHECK LIST

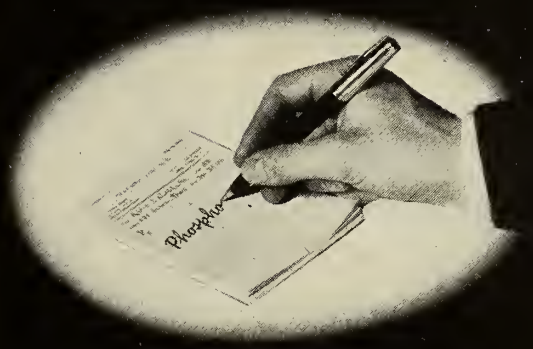
for choice of a laxative

Phospho-Soda (FLEET) TYPE OF ACTION

- ✓ Prompt action
- ✓ Thorough action
- ✓ Gentle action

•

SIDE EFFECTS



- ✓ Free from Mucosal Irritation
- ✓ Absence of Constipation Rebound
- ✓ No Development of Tolerance
- ✓ Safe from Excessive Dehydration
- ✓ No Disturbance of Absorption of Nutritive Elements
- ✓ Causes no Pelvic Congestion
- ✓ No Patient Discomfort
- ✓ Nonhabituating
- ✓ Free from Cumulative Effects

•

ADMINISTRATION

- ✓ Flexible Dosage
- ✓ Uniform Potency
- ✓ Pleasant Taste

Phospho-Soda (Fleet) is a solution containing in each 100 cc. sodium biphosphate 48 Gm. and sodium phosphate 18 Gm.

Judicious Laxation

...through freedom from undesirable side effects

The clinical preference for Phospho-Soda (Fleet)* stems in large part from its freedom from undesirable side effects. This desideratum, together with its controlled action and ease of administration, assure safe, effective anticostive therapy from every prescription of this "tried and true" laxative agent. Clinical samples on request.

DEVELOPED FOR YOUR DIET KITCHEN
Rochester
Dairy
EVAPORATED SKIM MILK
NON-FAT DRY MILK SOLIDS
High in protein, low in fat, both Rochester Dairy Evaporated Skim Milk and Rochester Dairy Non-Fat Dry Milk Solids can be valuable for high caloric feeding and in diets where it is necessary to add large amounts of readily-available protein.
Three important reasons for choosing Rochester Evaporated Skim Milk and Rochester Non-Fat Dry Milk Solids are:
1. High palatability
2. Low cost
3. Constant and easy availability to all hospitals
If you specify Rochester, you'll have the added advantage of Rochester Dairy's famous quality control program, one of the most outstanding in the country. Write today for free samples.

POSTOPERATIVE COMPLICATIONS OF THYROIDECTOMY

DONALD C. MACKINNON, M.D., F.A.C.S.
Minneapolis, Minnesota

THIS review will deal with the etiology, symptoms, treatment, and prevention of postoperative complications of thyroidectomy.

These complications may be due to hemorrhage, severe hyperthyroidism, tracheal obstruction, accidental removal of parathyroid glands, accidental injury to the recurrent laryngeal nerves, as well as to the removal of too much or too little thyroid tissue. The circumstances which may produce such a set of complications occur frequently. Moreover, they may be of such serious nature as to result in a permanently disabled patient or in an occasional death. Complications arising in the wound itself are important but are of a less serious nature. When strict attention is given to the improvements in preoperative and postoperative management, and a meticulous operative technique, the complications are, for the most part, avoidable.

Hemorrhage

Hemorrhage is a serious postoperative complication. It may cause sufficient pressure to produce complete tracheal obstruction, asphyxiation, and sudden death. When hemorrhage occurs beneath the skin flap the bleeding is usually venous in origin; but when beneath the sutured prethyroid muscles it is more often arterial in origin.

Hemorrhage under the skin flap may arise from the anterior jugular veins or from any of the small veins encountered in elevating the flap. This type of hemorrhage can be prevented by careful inspection of the wound and by securing accurate hemostasis of the bleeding points before the skin flap is replaced and the wound closed. When the prethyroid muscles are cut transversely the anterior jugular veins are severed (Fig. 1). To prevent severe postoperative hemorrhage from these vessels, a separate suture tie may be applied around them in addition to the mattress sutures employed in approximating the muscles transversely (Fig. 5). Subcutaneous hemorrhage occurs soon after operation, develops gradually, and is rarely of serious consequence. The patient complains of increasing pain in the wound. Inspection of the neck reveals abnormal oozing about the drains, if drains have been used, and a moderately tense bulging of the skin flap, which may be extensive when the hematoma is large. Hemorrhage from one of the anterior jugular veins develops rapidly causing extensive bulging of the skin flap. Unless there are symptoms of tracheal obstruction from pressure of the hematoma, the wound in subcutaneous hemorrhage is not opened at the bedside. Ordinarily there is sufficient time to move the patient immediately to the operating room where the wound is reopened, the blood clot evacuated, the bleeding point ligated, and the skin flap replaced. Hematomas of moderate size, in which the bleeding has stopped, are best evacuated by opening the wound surgically. To attempt evacuation by partially opening the wound, inadequate probing, or trusting that the hematoma will be absorbed eventually will result in delayed wound healing and in excessive scar

formation. Furthermore, ineffectual probing may introduce infection into the hematoma and result in marked disfigurement of the final goiter scar.

Postoperative hemorrhage beneath the prethyroid muscles of arterial origin is from the superior thyroid artery or from branches of the inferior thyroid artery in the remnant of the thyroid gland. Venous hemorrhage in this location is from the lateral thyroid veins or from their junction with the internal jugular veins. Venous hemorrhage may also occur from the inferior thyroid veins as they leave the inferior pole of the gland, or from injured veins in the depths of a substernal cavity from which a substernal goiter was evacuated. Bleeding points from these areas are overlooked, occasionally, when the wound is closed. Hemorrhage is due to inaccurate ligation of these vessels. The ligature slips off during the strain associated with postoperative coughing or vomiting, and the hemorrhage usually occurs within twelve hours after operation. However, a severe hemorrhage from a branch of the inferior thyroid artery has occurred as late as the eighth postoperative day.

Postoperative hemorrhage beneath the sutured prethyroid muscles is usually arterial in origin and constitutes a hazardous emergency. The life of the patient is threatened with dramatic suddenness. Bulging of the neck is not in evidence as observed when the hemorrhage occurs under the skin flap; rather, the neck is distended, tense, and indurated from hemorrhage into a tightly enclosed fascial space. There is sudden severe pain in the neck, anxiety, and interference with breathing due to tracheal obstruction or collapse. The pressure rapidly increases producing stridor, cyanosis, complete asphyxiation, and death—unless corrective emergency measures are instituted immediately. The interference with breathing develops so rapidly, producing such a hazardous and dramatic situation, that patients who have had a thyroidectomy should never be left with untrained attendants during the immediate postoperative course. These patients should always be observed by assistants or nurses trained to observe the symptoms of increasing tracheal obstruction due to arterial hemorrhage, and they should be qualified to act immediately when serious interference with breathing is present. A life can be saved, in a moment, by completely opening the wound at the bedside and removing the blood clots. This produces immediate relief of the tracheal obstruction. Gentle but firm pressure with a gauze pack is made over the bleeding point until the patient can be taken to the operating room where the bleeding points are accurately ligated and the wound closed.

During subtotal thyroidectomy there are technical measures that can be instituted to prevent, to a large degree, the hazards of postoperative arterial hemorrhage. Many of these technical points are advocated by Lahey.[6,8,10] They can be used only when the operation is performed with adequate exposure, in a dry field and with good illumination. A greater exposure can be obtained in large glands by cutting the prethyroid muscles transversely and reflecting them upward and downward away from the superior and inferior poles (Fig. 2). By mobilizing the gland from the thyroid bed and rotating it medially, adequate exposure is obtained for the dissection of the inferior thyroid artery. If the operation is performed in a blood-stained field there is greater danger of inadequate hemostasis, postoperative hemorrhage, and injury to the parathyroid and recurrent laryngeal nerves.

With the superior thyroid pole well exposed, with traction downward and medially, the superior thyroid arteries can be dissected out from the surrounding areolar tissue and demonstrated as vascular trunks. A double ligature securely placed around these vessels is infinitely better than a single ligature. The ligatures should be placed approximately one millimeter apart so that the vessels are ligated at two separate points (Fig. 3). The vessels should not be cut too close to the inferior ligature. No matter how high the superior pole ascends it must be exposed so that the superior thyroid vessels can be accurately ligated without including a segment of thyroid tissue from the top of the superior pole in the ligature. If a mass of thyroid tissue is included with the vessels, it is impossible to tie the ligature tightly enough to prevent it from slipping postoperatively, during the strain produced by vomiting and coughing.

With the superior thyroid vessels and lateral veins ligated and cut and the great vessels of the neck retracted laterally, the lobe can be rotated medially, giving an adequate exposure for dissection of the inferior thyroid artery as a single trunk. It is found in the areolar tissue behind the gland, as it passes from behind the carotid artery to the posterior aspect of the gland, near the tracheo-esophageal angle. By ligating the inferior

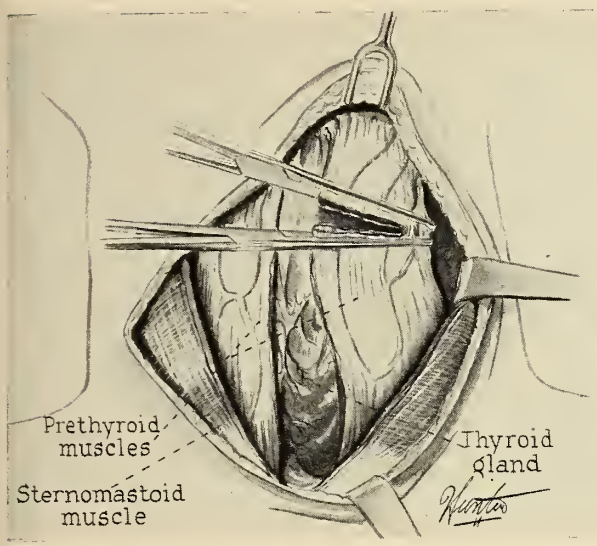

Fig. 1. Through a low curved collar incision, the skin, subcutaneous tissue, and platysma muscle are raised to the level of the notch of the thyroid cartilage. The medial border of the sternocleidomastoid muscle is freed, the prethyroid muscles split longitudinally, and cut transversely at a high level.

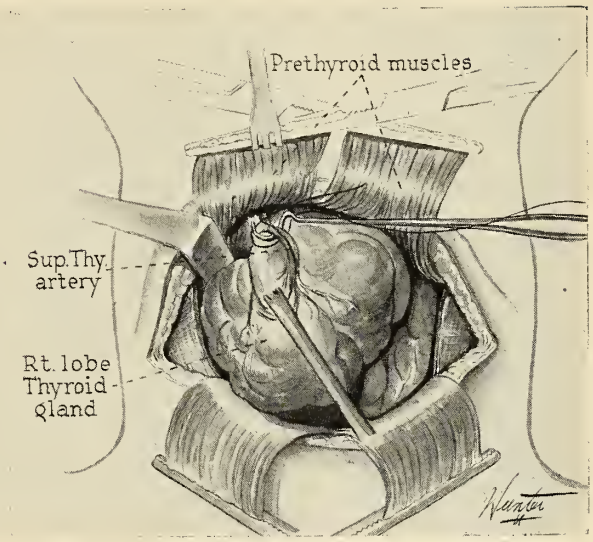

Fig. 2. The prethyroid muscles are reflected upward and downward exposing the thyroid gland. The superior pole is retracted downward, medially, and dissected free from the surrounding areolar tissue exposing the superior thyroid vessels for double ligation.

thyroid artery in continuity in its extracapsular course, bleeding from this vessel can be largely eliminated (Fig. 4). The vessel need not be ligated routinely; however, there is a distinct advantage in having it exposed, should troublesome hemorrhage arise from the remnant during the resection of the thyroid lobe. Diagramatically, the relationship of the branches of the artery to the recurrent laryngeal nerve is shown in Figure 6, *a* and *b*. If a hemostat is plunged into the remnant to clamp the artery, there is danger of injuring or ligating the recurrent laryngeal nerve. By rotating the hemostats and the gland medially, the hemorrhage can be controlled by ligating the inferior thyroid artery in its extracapsular course. Also, the surgeon's index finger may be used to compress the vessel against the cervical spine so that the bleeding remnant can be controlled, sponged, and the vessel individually snapped and accurately ligated. Mass ligatures and gland sutures have no place in thyroid surgery, if postoperative complications are to be avoided. Oozing from the thyroid remnant, which mainly comes from the terminal branches of the inferior thyroid artery, can be further prevented by suturing the lateral edge of the capsule of the remnant to the pretracheal fascia so that the cut surface is buttressed and compressed against the trachea (Fig. 4.) The surgeon must be careful not to indent or compress the trachea in accomplishing this phase of the technique.

A double ligature around the inferior thyroid veins, as they leave the inferior pole, is an additional measure of safety. Postoperative venous bleeding beneath the prethyroid muscles may arise from these vessels or from the lateral veins. Rarely must the wound be reopened and the bleeding point ligated. A careful inspection of the entire thyroid bed should be made in search of small points of oozing before the prethyroid muscles are sutured.

Thyroid Crisis

With the administration of the new antithyroid drugs for preoperative preparation, postoperative thyroid crisis or storm rarely occurs unless the patient with severe hyperthyroidism is inadequately prepared for operation. Clute[2] believes that, with improvement in the preoperative preparation of patients as practiced at the present time, serious thyroid storms can probably be avoided.

The etiology of a crisis is unknown. Thyroid crises have occurred in individuals with severe hyperthyroidism, especially in patients who resist, or respond poorly, to adequate preoperative preparation. A crisis may occur in elderly individuals, and patients over fifty years of age, or in those having hyperthyroidism for a year or longer. Other signs of dangerous toxicity may not be observed until the thyroidectomy is in progress. Marshall[4] states that during the first part of the operation severe hyperthyroidism is present if

NOTE: Figures 1 through 5 inclusive are the artist's illustrative reproductions made from the author's colored photographs taken during thyroidectomy at the Minneapolis General Hospital. The artist's sketches in Figure 6 were taken from illustrations by Lahey.[7,9]

there is a progressive rise in the pulse rate, a rising blood pressure with an increasingly widening pulse pressure, and an increasing demand for anesthesia depth with oxygen consumption over 600 c.c. of oxygen per minute. Conditions such as heart disease with decompensation, auricular fibrillation, pregnancy, diabetes, and acute infections increase the severity of hyperthyroidism and may be present in some cases of thyroid crises.

A postoperative thyroid crisis usually occurs during the first forty-eight hours, producing obvious symptoms and signs, indicating that a very serious state of toxicity is present or impending. The condition often begins with diarrhea and vomiting. The pulse rate continues to rise to exceptional rates, over 150. The temperature elevation is excessive, usually over 104 degrees. Sweating may be profuse. When dehydration occurs, the skin is dry and hot. Restlessness mounts into extreme activation. Psychic disturbances and a delirium which may become violent are present. There are periods of apathy, resembling coma. The condition is one of utmost gravity, from which the patient may not recover.

Postoperative storm is best prevented by adequate preoperative preparation and by limiting the extent of the thyroidectomy, according to the severity of the hyperthyroidism, and the operative reaction of the patient. The correct time for surgical intervention is when the patient has received the maximum benefit from his preoperative preparation. With the administration of the new antithyroid drugs, the pulse rate, basal metabolism, and weight should be normal. At the present time the possibility of a crisis can be reduced when the patient is properly prepared with adequate rest, sedation, a high carbohydrate diet, intravenous glucose, vitamin B complex, Lugol's solution, and propylthiouracil—or one of the new antithyroid drugs. As a last resort, the surgeon can interrupt the operation, when there are serious changes in the pulse rate, pulse pressure, or oxygen consumption, in order to avoid a crisis. Rea[14] recommends the use of spinal anesthesia as an adjunct to general anesthesia and to the operative management of severe hyperthyroidism, on the thesis that it would inhibit medullary adrenal releases during operation and forestall severe postoperative reactions.

When a thyroid crisis does occur, the postoperative therapy is intensified. In the presence of increased sweating, vomiting, and diarrhea, there is a greater demand for fluids, saline, iodine, and glucose. These are best administered by a constant intravenous drip. Ten per cent glucose provides calories and protects the glycogen stores in the liver which are being rapidly depleted during the crisis. Sufficient sedation in the form of morphine and barbiturates are given to control restlessness. The patient is kept in an oxygen tent; frequent sponge baths are given. According to Rea,[14] spinal anesthesia is also beneficial during a postoperative storm. Improvement is noted within twenty-four hours in favorable cases after these emergency measures are instituted. Such measures should be continued until all signs of active crisis have disappeared, at which time the usual postoperative therapy is administered until the patient leaves the hospital.

Tracheal Obstruction

Postoperative tracheal obstruction is caused by severe postoperative hemorrhage, edema, and collapse of the trachea. It frequently occurs as a late result of bilateral recurrent laryngeal nerve paralysis.

Tracheal obstruction produced by serious arterial or venous hemorrhage beneath the prethyroid muscles has been discussed. After the blood under tension is released and the hemorrhage is controlled, the symptoms of tracheal obstruction are relieved and tracheotomy is seldom indicated. If there is persistent difficulty in breathing after the tension is relieved, a tracheotomy should be done before the wound is closed. The edema of the larynx and upper trachea, associated with hemorrhage, may increase before it improves, especially following the manipulation and trauma of opening and closing the wound for a second operative procedure. It is an error to trust that the breathing will improve. Prolonged partial obstruction and anoxemia may result in a fatality if the operator postpones performing a tracheotomy. Whenever stridor, cyanosis, or any interference with breathing persists, tracheotomy is urgently indicated.

A gradual partial-tracheal obstruction may develop postoperatively due to edema. Edema of the wound spreading into the larynx or narrowed upper part of the trachea is caused by hemorrhage, infection, and surgical trauma. When symptoms of obstructive breathing develop as a result of edema, tracheotomy is indicated. Lahey[8] states that when in doubt, it is infinitely better to per-

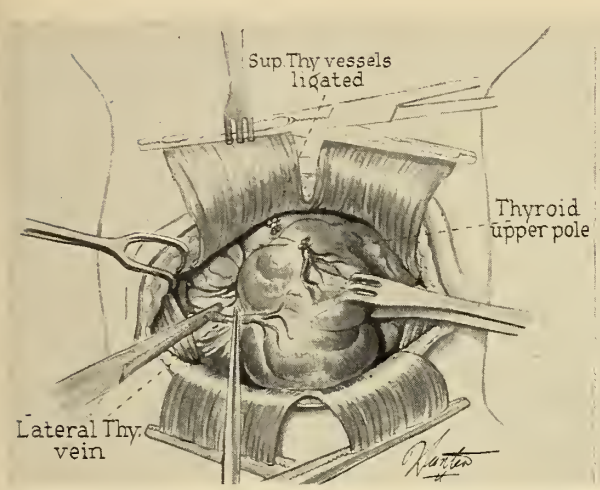

Fig. 3. The superior thyroid vessels are ligated and cut. The gland is rotated medially. The lateral thyroid veins are exposed, doubly clamped, cut, and ligated permitting further medial rotation of the gland.

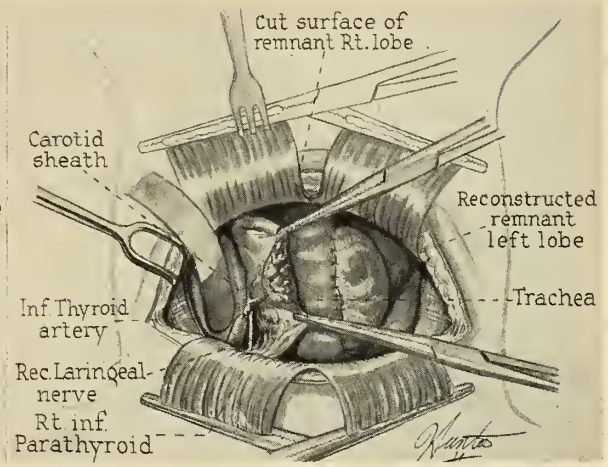

Fig. 4. The posterior surface of the gland is shown. The inferior thyroid artery is exposed and ligated in continuity as it passes from behind the carotid sheath to the gland. The course of the recurrent laryngeal nerve is shown. With the isthmus and the major portion of the lobes removed, the trachea, the cut surface of the right remnant, and the left remnant sutured to the pretracheal fascia are shown.

form an occasional unnecessary tracheotomy than to lose a single patient because of failure to take this precaution. Clute[2] states that tracheotomy should not be delayed in the presence of stridor. It is a serious error to await cyanosis, because the margin of safety is so narrow that any slight increase in obstruction may produce sudden death. The edema usually subsides within a week. The tracheotomy tube can be removed after the patient demonstrates that breathing has returned to normal.

Collapse of the trachea is a very rare postoperative occurrence. It has occurred in the presence of marked bilateral compression of the trachea due to long-standing pressure of an intrathoracic goiter. Collapse can occur during the operation after the pressure of the goiter has been removed. Apparently degenerative changes and atrophy of the tracheal rings account for the collapse. Carcinoma when directly invading the trachea may weaken the rings, with failure to restore an adequate airway, thereby necessitating tracheotomy. A noncollapsible endotracheal tube is frequently used in operating for intrathoracic goiters to avoid difficulties in administering an inhalation anesthetic, and to avoid complete tracheal compression during the extraction of the goiter. Then the collapse may not be apparent until after the tube has been removed. Ordinarily, the tracheal rings assume their normal outline when an intrathoracic goiter is removed and pressure is relived, but restoration of tracheal deviation is a more gradual process. The rare occurrence of tracheal collapse, whatever its cause may be, should be considered a cause of tracheal obstruction and treated by tracheotomy if serious interference of breathing is present. Tracheal obstruction may also occur as a late result of bilateral recurrent laryngeal nerve injury with bilateral paralysis of the vocal cords. During a six months' period, after injury to the recurrent nerves, the cords undergo atrophy and fibrotic contraction, bringing them close to gether in the midline. As the glottic space is narrowed, the patient's voice improves, but there is increasing difficulty in breathing. When the glottic space becomes so narrow that obstructive symptoms are severe (as indicated by the characteristic crowing on forced inspiration, stridor, and a sense of suffocation) a tracheotomy is indicated. In the presence of an acute upper respiratory infection and laryngitis, patients with bilateral paralysis of the vocal cords are in constant danger of suffocation. An emergency tracheotomy may be necessary in this condition.

Laryngeal muscle spasm is frequently observed as a patient awakens from an inhalation anesthetic. Usually the spasm can be relieved by administering oxygen and helium, atropine, or curare. Tracheotomy has been done when the condition persists.

An annoying complication occurs when a hole is accidentally made in the trachea. The opening must be closed by suture. When the mishap occurs in a

bloody field, aspiration of blood can be prevented by placing the finger over the hole until the field can be made dry and the opening closed.

Tracheotomy has been done high, just below the cricoid cartilage, because that is where the trachea is easiest to expose in the presence of a thyroid isthmus. Since the trachea is narrow at that level, it is incorrect to place a tracheotomy high. A stricture may develop due to cicatricial contraction and stenosis after the tube is removed. During thyroidectomy the isthmus should be removed and the trachea exposed. It is important to remove the isthmus (Fig. 4), not only in order to remove adequate amounts of thyroid tissue, but also because the trachea is then prepared, with valuable time saved, should a tracheotomy become necessary. In case of an emergency, one should then be able to do the tracheotomy quickly and easily at a lower level.

Parathyroid Tetany

Postoperative parathyroid tetany is caused by the removal of one or more parathyroid glands. Operative injury of the parathyroids, interference of their blood supply, thrombosis, edema, and fibrosis may also reduce parathyroid secretion sufficiently to produce transient tetany. Tetany will be permanent and complete if all parathyroids are removed, and will probably be transient and mild if only one or two glands are removed. Postoperative tetany is a rare complication and is usually transient when it does occur. In most large clinics, the incidence is less than 1 per cent. Bilateral ligation of the superior and inferior thyroid arteries does not appear to produce tetany.

In order to preserve normal parathyroid function, following thyroidectomy, the parathyroids should be preserved uninjured in their normal anatomical positions. A small strip of the posterior thyroid capsule extending from the superior to the inferior poles should be preserved, since parathyroid glands are most often located in that region. It is not necessary to search for the parathyroid glands routinely. However, during thyroidectomy, one should watch for them and be able to identify them. In order to locate, recognize and protect these small structures, it is necessary to have a thorough knowledge of their appearance and normal location. The structures are easier to find when an adequate exposure of the posterior capsule of the gland is obtained in a dry field and under good illumination. A magnifying lens will aid in identifying them.

The superior parathyroids are most constantly found near the posterior aspect of the upper pole of the thyroid gland where it rests laterally against the trachea and larynx. The inferior parathyroids are most often found on the posterior capsule of the thyroid gland, in close relation to the branches of the inferior thyroid artery (Fig. 4). However, parathyroids may be found in atypical positions such as within the gland, on the anterior or lateral surface, or well outside of the gland, and in the mediastinum. Their color is light mahogany-brown. They are about one-half the size of a small pea, have rounded edges, and are covered by a glistening capsule. The texture of the parathyroids is more firm than a globule of fat. Being supplied by an end artery, they appear to be movable on a narrow pedicle. By observing these characteristics of parathyroids, one can preserve them in most instances. However, one can never be certain that a structure is a parathyroid gland except by microscopic examination. Occasionally a structure is left in situ, on the assumption that it is probably a parathyroid without its identity being absolutely established. In large adenomatous goiters, intrathoracic goiters, and in cases of recurrent hyperthyroidism, injury to the parathyroids is more frequent because there is greater variation in their location. Greater care is necessary in operating on these patients if injury to the parathyroids is to be avoided.

Transplantation of parathyroids from one individual to another offers little chance of restoring normal parathyroid function. Auto-transplantation, as practiced at the Lahey Clinic, may be of benefit, though the actual value of the procedure is difficult to evaluate. Parathyroids are accidentally removed often enough to warrant a careful routine search for them on the surface of the resected thyroid tissue. If a suspicious parathyroid body is found, a tiny biopsy is taken for subsequent microscopic verification and the tissue is transplanted into a dry pocket made in the belly of the sternomastoid muscle before the wound is closed. Cattell[1] has shown that in 472 possible parathyroid implantations, 160 (34 per cent) were actually parathyroid glands by microscopic examination. None of these patients developed postoperative tetany.

Severe tetany occurs within two or three days postoperatively, whereas the milder forms develop later. In tetany there is an increased irritability of the peripheral motor nerves. The patient complains of stiffness in the muscles of the hands, legs, face, and neck. There may be cramps and muscular twitchings of the muscles of the extremities and face. Marked muscle spasm occurs in the hands when the nerve trunk is deprived of its circulation by means of a blood pressure cuff. This response is due to asphyxia, and is called Trousseau's sign. The facial and abdominal muscles may be forced to contract violently by the mildest stimuli. Spasms are painful and may occur spontaneously. Contraction of the facial muscles can be produced by mechanical stimulation, Chvostek's sign, when the facial nerve is gently tapped in front of the ear. Numbness and tingling of the face, hands, feet, and legs may be present. Erb's sign is elicited when muscular contraction is produced by stimulating a motor nerve with a much weaker galvanic electrical stimulus than is normally necessary. The response is obtained with less than 5 ma., while normally over 6 ma. are required. Tetany of longer duration produces ectodermal changes, such as bilateral cataracts, courseness and thinning of the hair, and rigid nails. Gastrointestinal disturbances occur with abdominal pain, and alternating constipation and diarrhea. Excitement, exertion, and overbreathing may precipitate an attack of muscle spasm. Epileptiform convulsions, hyperpnea, salivation, severe depression and death will occur in permanent and untreated tetany.

There is a decreased concentration of serum calcium from a normal of between 10 and 12 mg. per cent, to 8 and 6 mg., or even lower; with an elevation in the serum phosphorus from the normal of 3 or 4 mg. per cent, to 6 or 8 mg. per cent. A blood calcium of 7 or 8 mg. per cent is usually found in transient or latent tetany. Presumably, the hyper-irritability of the motor nerves is due to a diminished amount of ionized calcium in the blood.

According to MacBryde,[11] the treatment of hypoparathyroidism may be considered under two headings: (1) the acute attack, and (2) chronic tetany.

A patient may die in the acute attack from severe laryngeal spasm, diaphragmatic spasm, or from repeated epileptiform convulsions. Prompt and effective treatment is necessary. Intravenous calcium is given. Calcium chloride is very irritating to perivascular tissues if leakage occurs. From 10 to 20 c.c. of a 5 per cent solution will terminate most attacks abruptly. Calcium gluconate is less irritating to the tissues and can be administered intravenously or intramuscularly in doses of 10 to 20 c.c. of a 10 per cent solution. The blood calcium will be restored to normal promptly, but the effect is transient in severe tetany. Within one to four hours the serum calcium will fall to its previous level. The intravenous injection may be repeated once or twice if necessary until other therapeutic measures become effective. One to three cubic centimeters of parathyroid hormone (100 U.S.P. units per c.c.) should be given intravenously or intramuscularly immediately after the calcium is administered. Within a few hours the serum calcium is raised. The peak effect is from eight to eighteen hours, while all effect is lost in from twenty to twenty-four hours. Daily injections of the extract are required in a patient with severe hypoparathyroidism. The disadvantages of the extract for continued therapy is that it is expensive, inconvenient to administer, and the patient usually develops a tolerance so that larger doses are required; and finally little or no response occurs.

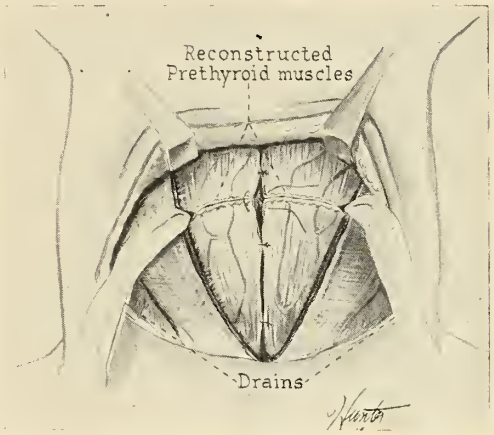

Fig. 5. The prethyroid muscles are reconstructed using fine Lembert and Halsted mattress sutures. Small rubber drains placed in each thyroid bed are brought out laterally through the prethyroid muscles and skin incision.

The treatment of chronic tetany should begin immediately after the acute attack and as soon as it is evident that the patient cannot maintain a normal serum calcium level. A high oral calcium intake should be administered. From 5 to 15 gms. of calcium lactate or gluconate daily are usually advisable. MacBryde[11] has found that

this amount of calcium is not disagreeable. It reduces the cost of treatment, since the dose of dihydrotachysterol varies with the severity of the case and the amount of calcium ingested. Dihydrotachysterol (Hytakerol) will maintain serum calcium within normal limits even in the most severe cases of hypoparathyroidism. It is taken orally in capsules containing 2.5 mgs. or in a 0.5 per cent solution, 1 c.c. representing 5 mg. The initial and maintenance doses are given according to the serum calcium levels. Two to four teaspoonfuls of calcium lactate or gluconate are taken throughout the day. The serum calcium can be raised more rapidly if four capsules (2 c.c.) daily are given for three days, then two capsules (1 c.c.) daily until the serum calcium level is 9 or 10 mg. One capsule (0.5 c.c.) daily, or less often, is the usual maintenance dose which must be determined for each individual patient. By using this schedule the normal serum calcium is reached within seven to ten days. When the drug is stopped the calcium level falls slowly, over a period of two to three weeks. The advantages of dihydrotachysterol is that it is effective orally, is stable, is less expensive, has a prolonged action, and the patient does not develop a tolerance. Frequent blood calcium determinations are necessary until the maintenance dose is established; then it need be determined only every two or three months. The amount of calcium excretion in the urine can be determined by the Sulkowitch test which will give rough estimations of the blood calcium levels. In excessive amounts, the drug may cause hypercalcemia and severe toxic effects.

According to MacBryde,[11] Vitamin D concentrates in doses of 50,000 to 150,000 units with large doses of calcium lactate or gluconate taken orally will give similar results to those obtained with dihydrotachysterol.

Dessicated thyroid promotes calcium absorption and tends to maintain a normal serum calcium when hypothyroidism as well as hypoparathyroidism is present. The dose is based on the amount required to restore the basal metabolic rate to normal.

Recurrent Laryngeal Paralysis

Injuries to the recurrent laryngeal nerve occurring during thyroidectomy are due to cutting, crushing, or including the nerve in a ligature. Lahey[7] has shown in over 10,000 recurrent laryngeal nerve dissections that the nerve withstands dissection, gentle handling, and palpation while slightly stretched without immediate or delayed interference with function.

Most recurrent nerves are injured high in their extralaryngeal course at a point below where the nerve passes under the lower border of the inferior constrictor muscle of the pharynx to become intralaryngeal. At this level the nerve passes very close to the superior branch of the inferior thyroid artery, as the artery ascends in the thyroid gland close to the upper part of the trachea or the cricoid cartilage (Fig. 6, *a* and *b*). This vessel is frequently torn during resection of the thyroid lobe so that a hemostat plunged into the remnant as the vessel retracts, may also grasp the nerve. Injury to the nerve at a lower level is much less common, because the course of the nerve from its lower tracheo-esophageal position is obliquely upward, forward, and inward toward its extralaryngeal termination. The nerve may pass behind or in front of the inferior thyroid artery, or between its bifurcation (Fig. 6, *b*, *c*, and *f*). Occasionally an anomalous recurrent nerve will pass at a higher level directly from the vagus nerve to the larynx (Fig. 6, *d*), or it may descend only to the level of the inferior thyroid artery, around which it passes before ascending to the larynx. There may also be a rare anomalous extralaryngeal division of the nerve into adductor and abductor fibers before it enters the larynx (Fig. 6, *e*). The surgeon must be aware of the occasional existence of these anomalies to avoid injury to the nerve during its dissection. The nerve is in danger when surgery is performed for large adenomas adjacent to the posterior capsule, intrathoracic goiters, recurrent hyperthyroidism with excessive scar formation, or when a total lobectomy is necessary. In such cases the nerve may be displaced, or so closely encroached upon, that it must be exposed in order to avoid injuring it.

The nerve contains abductor and adductor fibers carrying impulses which produce opposing muscle actions. In addition, there are co-ordinating impulses concerned with speech and breathing. A rare condition of serious interference with breathing could occur during operation in a patient whose recurrent nerves divided into adductor and abductor fibers before entering the larynx, provided bilateral injury occurred, selecting only the abductor fibers of the bifid nerves.

The cords would then be adducted, the glottic space narrowed, and immediate serious obstructive breathing could then occur.

Injury to one recurrent laryngeal nerve results in a flaccid paralysis of the cord. In a few months the cord becomes fixed in the midline, due to atrophy, fibrosis, and contraction. There is usually no interference with breathing because the normal cord can be abducted sufficiently to provide an adequate airway. Occasionally an audible stridor can be heard in these cases after marked physical exertion because the glottic space is narrowed by the paralyzed cord. There is usually an immediate change in the voice which is largely overcome by compensation as the normal cord approximates itself to the paralyzed cord. However, unilateral injury frequently passes unnoticed by the patient and the surgeon. The only inconvenience may be a cracking of the voice when used with force. The diagnosis should be established by careful laryngoscopic examination. The cords should be examined in all cases operated upon for recurrent hyperthyroidism. If a unilateral paralysis of the cord is discovered, the normal recurrent nerve must, by all means, be preserved if a bilateral paralysis is to be avoided.

When both recurrent laryngeal nerves are injured, the innervation of both vocal cords is lost, including the ability to adduct or abduct the cords. They become flaccid and assume the cadaveric position. Difficulty during the operation in the patient's breathing is rarely encountered. Postoperatively, the patient is unable to tense or adduct the cords, so that the voice is lost for anything more than a whisper. Usually the voice begins to return within six months. As a result of atrophy, fibrosis and contraction of the cords, the laxity disappears, the cords become more tense, and the voice partially returns. As the process continues and the glottic space is narrowed, there is further gradual improvement in the voice. However, about this time the patient begins to have difficulty in breathing through the fixed narrowed glottic space; the cords vibrate, producing the characteristic crowing sound heard on forced inspiration associated, sometimes with the slightest exertion or physical activity. A laryngoscopic examination will reveal the paralyzed cords. The activity of some of these patients may be markedly limited by the interference with breathing so that a tracheotomy is indicated. These patients may become anoxemic with the slightest exertion. An emergency tracheotomy is indicated if an acute laryngitis precipitates suffocation.

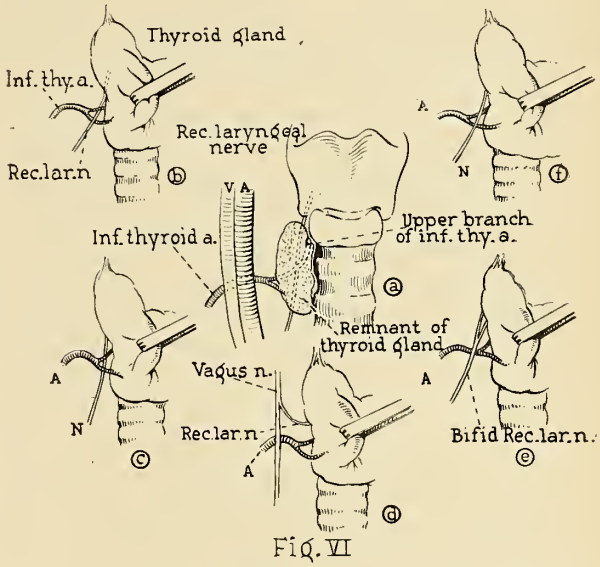

Fig. 6. Sketches showing *(a)* the diagrammatic relationship of the inferior thyroid artery and the recurrent laryngeal nerve to the remnant of the thyroid gland; *(b, c, d, e, and f)* the variable course of the recurrent laryngeal nerve in relation to the inferior thyroid artery.

There are several procedures available to patients with long standing abductor paralysis. A permanent tracheotomy with a flap valve which automatically closes on expiration can be performed. This will give an adequate airway and will allow the patient to speak to the degree that the voice had previously returned. The operation practiced by Lahey and Hoover[9] is a submucous resection of one of the paralyzed cords. The operation provides an adequate mucous membrane lined airway in the larynx, but there is further loss of voice which resembles a hoarse whisper. The advantage of the procedure is that a permanent tracheotomy tube is no longer necessary. This is also true of the King operation or its modifications. In the operation of laryngoplasty described by King,[3,5] the arytenoid cartilage is dislocated, rotated, and pinned back to the thyroid cartilage by two extralaryngeal stitches so that an adequate airway is provided with little, if any, change in the voice. Kelly[4] modified the King operation by excising the arytenoid cartilage extralaryngeally through a window in the thyroid cartilage. Wright[15] advocates that, after the arytenoid cartilage is delivered, the posterior end of the vocal cord be sutured to the external peri-

chondrium so as to secure a wider glottic space. In the McCall and Gardiner[13] modification of the King operation, the arytenoid cartilage is not removed, but anchored in the window of the thyroid cartilage using a direct laryngoscope as a guide. Late anastomosis of injured recurrent nerves has not been successful. Within six months the vocal cords become fixed, contracted, with ankylosis of the arytenoid cartilages. If nerve regeneration does take place, the cords are too fixed to respond to their impulses. Whether a small nerve containing both adductor and abductor fibers and carrying impulses with opposing muscle actions can regenerate, restoring normal function, is not definitely known. Whenever an anastomosis of the nerve is undertaken, the anastomosis should be done early with a true anatomical approximation. If a bilateral nerve injury is discovered while the patient is still on the operating table, Lahey[7,8] advises that the wound be reopened and a repair attempted. If the injury is not discovered until several hours after the operation, he advises waiting for ten days to determine whether cord function returns. If it does not return and the patient's condition is good, he recommends early repair. This offers practically the only chance of restoration of function, since the arytenoid muscles are still movable and the cords are not fibrosed.

For over a period of ten years the dissection of recurrent nerves, as performed by Lahey[7] has been practically a routine procedure in thyroidectomy. It is recommended as a safe and justifiable procedure which diminishes, if not largely eliminates, injuries to the nerve. After adopting this procedure, a reduction in the incidence of recurrent laryngeal paralysis from 1.6 per cent to 0.3 per cent is cited.

Anyone trained to do thyroid surgery should know the course of the recurrent nerve accurately and be able to demonstrate it. The attitude that a nerve will never be injured if it is not seen and if a strip of thyroid tissue is left posteriorly, is false. Because of the danger of injuring the nerve, one should not persist in locating it in a blood-stained field, or under adverse circumstances. The nerve can be preserved by exposing it whenever the dissection or resection of the thyroid encroaches upon its course. Adequate exposure for this dissection is obtained after the superior thyroid vessels and lateral veins are ligated and severed so that the lobe can be lifted from the thyroid bed and rotated medially (Fig. 4). The carotid sheath is freed from the gland and the great vessels of the neck retracted laterally. The inferior thyroid artery is demonstrated in the fine areolar tissue in this area between the esophagus and the trachea. At this point the recurrent nerve passes upward, forward, and inward, adjacent to the trachea toward the bifurcation of the inferior thyroid artery (Fig. 4 and 6). If the areolar issue is stained with blood, the color and the appearance of the anatomical structures will be so disturbed that the dissection will be difficult or impossible without greatly endangering the nerve. Unless there is an adequate exposure, a dry field, and a good light, the nerve should not be dissected.

Hypothyroidism and Persistent Hyperthyroidism

Postoperative hypothyroidism and persistent hyperthyroidism are a result of removing too much or too little thyroid tissue. One can have a more accurate understanding of this problem if the amount of tissue left as a remnant is indicated, rather than the amount of tissue removed. Roughly, the remnant may be designated as being small, moderate, or large in size. Several factors influence the amount of gland to be left behind as a newly constructed thyroid remnant. With a knowledge of these factors, the surgeon may still not succeed in accomplishing an accurate resection, or tailoring a remnant of appropriate size for every individual. If an error must be made, it is infinitely better in most cases to take a little too much than too little tissue. A mild degree of hypothyroidism can be satisfactorily controlled medically with thyroid extract.

A radical resection should be done in individuals with severe hyperthyroidism, who have large glands, who are young and who have had the disease for a long period of time. Patients resisting preoperative preparation should also have more radical resections. Before the days of thiouracil, when iodine alone was used for surgical preparation, the degree of involution of the gland was considered to be a most important factor. A well involuted gland shrinks markedly, becomes firm, pale, and avascular. A more radical resection was indicated in the glands that did not involute well. A more radical resection is usually done in exophthalmic than in adenomatous

goiter and patients with recurrent hyperthyroidism obviously require a more radical resection.

A less radical resection should be done in mild hyperthyroidism, in older individuals, and in children. The patients showing a good response to surgical preparation and good involution of the gland should have less radical resections. Children with hyperthyroidism should be left with more thyroid tissue than is left in the adult as postoperative myxedema in a child interferes with normal mental development and growth, and is to be avoided.

Persistent and recurrent hyperthyroidism are often a result of inadequate resection or attempting to do a subtotal thyroidectomy without adequate exposure, or adequate mobilization and rotation of the thyroid lobes. Large sections of the posterior aspect of the gland and retrolaryngeal extensions are often overlooked. Leaving portions of a hyperplastic isthmus or a pyramidal lobe may also cause recurrences.

Tracheal Irritation

Following a thyroidectomy, there is frequently some degree of tracheal irritation or tracheitis, with cough, and expectoration of mucus. It seems to be caused by rough handling of the larynx and trachea in difficult goiters with retrolaryngeal and substernal extensions. The dissection of the isthmus from the front of the trachea causes little difficulty. Mild irritation usually disappears in a day or two without special treatment. In other cases, steam inhalations make the patient more comfortable, loosens the mucus, and facilitates expectoration. If mucus accumulates in the trachea or upper respiratory passage during operation, an intratracheal catheter should be passed to suck it out. Anesthesia through an endotracheal tube, properly introduced, is deal for thyroidectomy. An airway is maintained at all times. Tracheal secretions can be aspirated during, and at the end of the operation. If sufficient mucus develops postoperatively to interfere with the patient's breathing, suction bronchoscopy should be instituted immediately. This is the safest means of preventing or treating an atelectasis.

Exophthalmos

Ocular complications may occur in patients having severe exophthalmos. If the eyes are left unprotected by incomplete closure of the lids, the eyes may be injured during the operation or early in the postoperative course. Conjunctivitis, injury to the cornea, corneal ulcers, or other injuries to the eye may occur. The eyes should be protected during the operation with an ophthalmic lubricant and vaseline strips. It may be necessary to suture the lids closed before operation and leave the sutures in place for a few days when the exophthalmos is severe in order to protect the eyes. Following thyroidectomy, the exophthalmos gradually improves in most cases. Rarely, in severe exophthalmic goiter, a progressive exophthalmos may develop postoperatively with marked protrusion of the eyeballs and permanent loss of the eyes. A competent ophthalmologist should observe and treat these eye complications.

Wound Complications

Wound complications following thyroidectomy are usually not serious. An acute infection of the wound rarely occurs. Occasionally a generalized brawny edema of the muscles, fascia, and skin flap is observed postoperatively. This will quickly subside with the application of hot packs. Small collections of serum beneath the skin flap will be absorbed in a short time. Larger pockets or collections of serum should be drained by probing through a small opening in the incision. Occasionally, a small rubber tissue drain may be inserted until the walls of the space collapse and become adherent. Deep induration and swelling of the wound may be present for five or six weeks, especially if the muscles have been cut transversely.

Lahey[6,10] advises drainage of the thyroid bed through the lateral angles of the wound. Kocher drained his cases through a stab wound below the incision. This adds an additional scar which may be quite unsightly, though the goiter scar may be excellent. It then became customary to insert the drains in the midline through the incision but this is undesirable because the drains pass between the separated fibers of the prethyroid muscles, so that when the drains are withdrawn, adhesions form between the skin, subcutaneous tissue, and trachea. These adhesions either contract and distort the incision, or the scar may ascend or descent with the trachea with each act of swallowing. If drainage following thyroidectomy is instituted, a small Penrose drain may be placed in each thyroid bed and brought out laterally through the prethyroid

muscles and skin incision (Fig. 5). There will be less danger of adhesions distorting the goiter scar in this position; also, the skin closure is flexible over the fascia and underlying muscles. The drains are removed in twenty-four to forty-eight hours, depending upon the quantity of serosanguinous drainage present. When the surgical field is unusually dry, the wound may be closed without drainage. Better looking scars result when drains are removed early or not employed at all.

When drains are placed in a deep mediastinal pocket, left after the removal of an intrathoracic goiter, the drains should not be removed until the pocket has collapsed and its walls become adherent. Lahey[8] advises draining these cavities from seven to eight days, plus following the removal of the drain with a baby catheter until the cavity is completely obliterated. Fluid will accumulate in these cavities if they are not allowed to collapse, or if the drains are removed too early.

The skin clips are applied loosely and removed on the second and third postoperative days. If the skin clips are left in too long, the small barb on the clip will produce pressure necrosis, causing unsightly puncture scars which are much like the scars seen where coarse, interrupted, nonabsorbable sutures are employed. Even though the skin clips are removed early, the skin incisions do not break open. Postoperative thyroid patients have marked discomfort, even with limited extension of the neck, which serves as a protective mechanism so that traction placed on the skin incision is insufficient to produce a wound separation or have any influence on the final width of the scar. A uniform, moderate pressure bandage applied over the wound during the first forty-eight hours will reduce the incidence of serum collections beneath the skin flap.

The incision is a low, curved collar-incision placed the breadth of one finger above the clavicle and two fingers above the sternal notch. In glands with a greater outward growth, the incision is made a little higher to allow for more of a drop in the final scar. Ordinarily, the final scar is located at the junction of the neck and chest where it can be easily concealed in women with a necklace. When the scar and underlying fascia become adherent, producing an irregular angulation of the incision after primary healing takes place, the final appearance of the scar can be greatly improved by massaging and stretching the incision to lengthen the adhesions. A revision of the incision should not be attempted within a year; and then a revision is seldom necessary. Lahey[8] states that keloids respond poorly to postoperative irradiation. He prefers to treat them by excision, followed by irradiation of the incision within a week in order to prevent the formation of another keloid.

Routine chest roentgenograms are now made on all patients at the time of their admission to all (Veterans Administration) hospitals and on all veterans who visit our outpatient departments for pension or compensation examinations, unless they have been examined within the previous six months. In addition to this, annual roentgenograms are to be obtained for all hospital employes and all patients who are hospitalized for more than one year.—John B. Barnwell, M.D., *Am. Rev. Tuberc.*, July, 1948.

THE CONTROL OF TUBERCULOSIS IN MINNESOTA

PHILIP R. BECKJORD, M.D., LT. COL., M.C., U.S.A.
Minneapolis, Minnesota

THE MIDWESTERN state of Minnesota, having an area of 84,068 square miles, a population in 1940 of 2,792,300 and being an agricultural and mining area, enjoys one of the lowest mortality rates from tuberculosis in the United States.[4,6] In 1946, the comparative statistics relative to tuberculosis in Minnesota stood as shown in Table I.

TABLE I. COMPARATIVE RATES FOR TUBERCULOSIS MORTALITY AND BEDS PER ANNUAL DEATH, 1946.

	Mortality Rate per 100,000	Beds per Annual Death
Minnesota	21.1	3.54
United States	35.9	1.70

Despite this favorable position among the several states and continually improving tuberculosis control program the public health leaders of the state estimate that there are still some 2,500 cases of active tuberculosis within the eighty-seven counties of Minnesota. It is probable, however, that the relative wealth of the area, the absence of overcrowding, the vigorous stock of the people, and the long freedom from war on home soil have all exercised a beneficient effect on tuberculosis morbidity in the past.

Role of the State Health Department

The basic control of tuberculosis in the state of Minnesota is carried out essentially by the medical practitioners of the state. The impetus for continuing routine control measures and beginning new ones is given, however, by the state health department through its small but active Division of Tuberculosis.

The staff of the latter unit consists of: a director, qualified by holding the M.D. and M.P.H. degrees; a central office force of nine persons, mostly secretarial; a field service of three public health nurses; and four mobile unit x-ray technician-drivers.

Through his parent unit, which is the Section of Preventable Diseases, the director of the Division of Tuberculosis has access to the complete tuberculosis reports of the state. These reports include a life file, which lists all living reported cases of tuberculosis in the state back to the year 1913, a death report file and a visible county index file, which notes all those persons in the life file who are in need of medical or nursing supervision. The latter index is most useful, since the staff may, theoretically at least, follow the history of any active case in the state until a cure or death occurs. It is obvious, however, that such a file is far from complete because of the fact that in 1945, 15 per cent of tuberculosis deaths were first reported as cases of tuberculosis at the time of death.[6]

The usefulness of the county index file is dependent upon the co-operative response of practicing physicians and patients to the stimulating letters or visits from the state Division of Tuberculosis staff. Remote control supervision of those active cases in sanatoria can be safely left to the sanatoria; keeping track of the non-sanatorium or ex-sanatorium patient is a more difficult matter. The state office urges those counties that have a public health nurse in attendance to maintain a similar file, follow-ups to be carried out by the nurse.

If an individual carried on the county index file does not answer a query of the state office, and a possibility of infectiousness exists, the case is investigated by an epidemiologist from the state office.

An important work carried on by the Division of Tuberculosis is that of conducting mobile chest x-ray unit surveys throughout the state. There are six such units in Minnesota, three of which are owned by the state; and the remaining three are stationed in and owned by local voluntary societies in St. Louis, Ramsey and Hennepin counties, respectively. The cost of these 70 mm. serial x-ray mobile units, including truck and trailer, runs between 19,000 and 25,000 dollars each.

The surveys are done by county area and upon request of the individual counties. The three state-owned units are almost constantly in operation. Request for a survey is often initiated by the county medical society and must, in any event, be approved by the county medical society and the local tuberculosis sanatorium, if any. Final decision is made by the director of the

Dr. Beckford is a Lieutenant Colonel in the Medical Corps, U. S. Army

Division of Tuberculosis.[7] To date, all but 15 counties have made requests for a survey. There is a backlog of forty counties to be surveyed.

As yet no county has been surveyed twice, with the exception of St. Louis county. A prerequisite to the conduct of any survey is that at least one public health nurse be available in the county to carry out the neeessary follow-up work obviously mandatory for the success of the program. Such a prerequisite has been instrumental in causing many counties to engage the services of a public health nurse on a permanent basis. A further vital requirement to the success of the procedure is the wholehearted co-operation of the people of the area. In fact, in addition to furnishing personnel, educational propaganda effort, office space and material, voluntary agencies must bear the total cost of the local administrative expenses of such a venture, estimated to amount to 15 cents per film. Each film costs approximately 55 cents in figuring the operating expenses of a unit; 45 cents per film is paid by state and Federal funds allocated for this purpose. During the six months ending in June, 1948, five units (two county, three state) x-rayed 163,000 persons and discovered 1,000 reinfection (adult type) cases of tuberculosis, an incidence of .614 per cent. Seventy-five per cent of these cases were previously not known to health departments.[6]

Exact details of the mobile x-ray unit surveys, as carried out in Minnesota, have been adequately described by Mark[7] and will not be repeated here. However, a previously published[5] flow chart, prepared by the Division of Tuberculosis, is presented in Chart 1 as being of value in giving a comprehensive graphic view of a mobile unit survey.

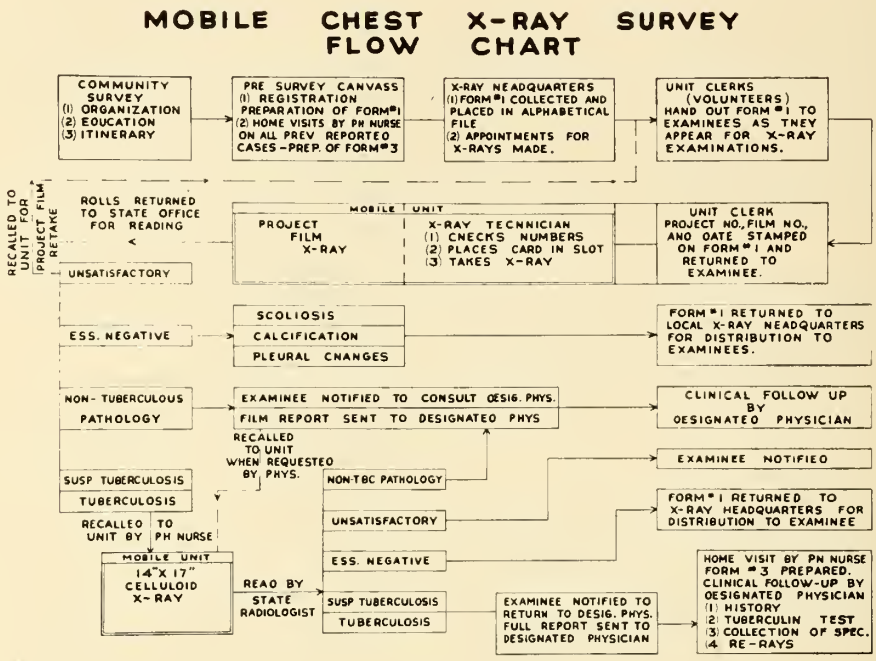

Chart I.

Effective as the mobile unit surveys are in bringing to light cases of tuberculosis, as is indicated in the six months' figures above, it is to be noted that the entire program is voluntary; and, as such, is subject to the defaults of recalcitrant free people. Further, it is impossible to screen more than 75 per cent to 94 per cent of a population of five years of age and above in any given area, during any one survey. Thus, even in surveyed areas, 6 per cent to 25 per cent of the population always escapes examination.[6] The question of time lag also arises. One survey unit can screen 2,000 chests per week on the average. Minnesota, with a population of 2,792,300, could, theoretically, be screened on a state-wide basis in one year by twenty-seven units. The presently available six units, assuming that all six could work constantly, would then require four years to x-ray the entire population. From an economic standpoint it would be impractical to depend upon mobile x-ray units for annual state-wide case finding surveys.

TABLE II. TUBERCULOSIS SANATORIA OF MINNESOTA, 1948

Sanatorium	*Location*	*Beds*	*Counties Served*	*Year Opened*
Minnesota State	Walker (Ah-Gwah-Ching)	355	43	1907
Nopeming	Duluth	275	1	1912
Otter Tail County	Battle Lake	48	1	1913
Ramsey County*	St. Paul	275	1	1914
Mineral Springs	Cannon Falls	100	8	1915
Glen Lake	Oak Terrace	639	1	1916
Sunnyrest	Crookston	60	2	1916
Lake Julia	Puposky	52	4	1916
Sand Beach	Lake Park	42	2	1916
Riverside	Granite Falls	48	4	1917
Buena-Vista	Wabasha	30	2	1917
South Western Minnesota	Worthington	54	10	1917
Oakland Park	Thief River Falls	65	4	1917
Fair Oaks Lodge	Wadena	36	2	1918
Deerwood	Deerwood	26	2	1918
Total		2105	87	

*Includes the Ramsey County Pavilion, a wing of Ancker General Hospital, St. Paul.

The additional twenty-one units, which would be required, alone, not including personnel salaries, would cost $525,000. At 55 cents per film, the cost per annum for the state's people would amount to $1,525,000.00. However, using the presently available machines, the cost on a five-year cyclic continuous mass survey basis would be about $300,000.00 per anum. Whether this latter sum would be balanced in cutting sanatoria operating costs, sickness and unemployment payments, et cetera, is an open question.

Tuberculosis Sanatoria in Minnesota

Since general hospitals in the State (two exceptions in St. Paul and Minneapolis) do not list beds for care of the tuberculous, only sanatoria can be discussed in relation to tuberculosis hospitalization. Minnesota has one state sanatorium, fourteen county sanatoria but no private sanatoria. Distribution of the 2,105 available sanatoria beds and the number of counties serviced by each institution is shown in Table II.

Surgical facilities for collapse therapy among the sanatoria are available only at Ah-Gwah-Ching, Glen Lake, Ramsey Pavilion, Mineral Springs and Nopeming. The smaller institutions all have pneumothorax and x-ray services, but patients must be sent to local general hospitals or to one of the large sanatoria for major surgical therapy. Sanatoria make an attempt to follow up all patients discharged from their confines.[13] There is no set pattern as to follow-up procedures. In some instances the institution has a public health nurse who actually visits the ex-inmate at his home. If the patient goes to a town outside of the county in which the sanatorium is located, public health personnel in the home area are invited to interest themselves in the case. As previously set forth, the Division of Tuberculosis keeps a live file on all cases of tuberculosis needing public health nursing or medical supervision, including discharged sanatoria patients. In all cases the physician of the discharged patient, if any, is notified by the institution of the patient's homecoming status.

It has been remarked by Smillie[12] that small sanatoria of less than 100 bed capacity are economically impractical. Although all but five of Minnesota's sanatoria fall within this category, it is unlikely that they will be closed if cognizance is taken of the cases of tuberculosis which are being discovered in the state in the amount of 0.6 to 1.5 per cent of all persons (.6 per cent rural to 1.5 per cent urban) examined by mobile survey units.[6] According to Mark,[7] 0.1 per cent of all persons so examined need hospitalization for observation or treatment. Thus it may be assumed that the state could, with six mobile survey units working, find up to 9,370 cases of tuberculosis in 1949, out of an anticipated 625,000 screenings, and have need to hospitalize some 625 of these. Such a requirement might continue annually until the entire population of the state has been screened, a matter of perhaps four or five years. During 1947 1,020 new cases, out of a total of 1,782 admissions, were admitted to all Minnesota sanatoria from all diagnostic sources. Should a continuous five year mass survey be put into effect in the state, it is estimated that total annual figures for sanatoria admission during those five years will rise by at least 30 per cent over the 1947 figure.

Tuberculin Surveys

With emphasis being placed on mass x-ray surveys in Minnesota,[2] the tuberculin survey is now considered primarily as a useful complementary case-finding method to be stressed until such time as mass x-ray surveys can be carried out to the optimum in degree and frequency. Initiative in stimulating tuberculin surveys is now in the hands of local health agencies, both official and voluntary. Most of the surveys are carried out on school children. The parents of positive reactors are notified and urged to have their children x-rayed. Local voluntary anti-tuberculosis agencies often finance such radiological follow-up

at no expense to the child's family. Although it is highly desirable that positive reactors to the Mantoux test receive chest x-rays, there is good cause to conduct the survey for statistical and epidemiological reasons. A tuberculin survey will give an index of the rate of infection in a community and is helpful in locating sources of infection. Duplicates of all survey records in Minnesota are forwarded to the Division of Tuberculosis.

The low incidence of sensitivity to tuberculin among the youth of the state is indicated in a report by E. A. Meyerding,[8] of the Minnesota Public Health Association, who gives the following figures for Mantoux test surveys in St. Paul high schools in 1947.

TABLE III—RESULTS OF MANTOUX TEST SURVEYS, 1947

Nine Junior and Senior High Schools, St. Paul, Minn.

Sex	Enrollment	No. Tested	Per Cent	No. Negative	Per Cent	No. Positive	Per Cent
Male	1,671	1,250	75.40	1,193	95.44	58	4.64
Female	1,709	1,457	85.25	1,385	95.05	71	4.87
Total	3,380	2,707	80.08	2,578	95.23	129	4.76

Tuberculin testing in the schools of the state seems assured for some time to come through the county accreditation plan,[9] standardized by the Minnesota Department of Health, the Minnesota State Medical Association and the Minnesota Public Health Association. The plan requires that for a county to be dubbed a "Tuberculosis Accredited County" by the Governor of the State, it must have a tuberculosis death rate of lower than 10.0 per 100,000 population per annum and a naturally occurring infection rate (i.e., not produced by BCG vaccination) among high school seniors of less than 15 per cent. The latter fact is determined by tuberculin surveys. To date, only fourteen counties, all rural, have been accredited.

The rather complex requirements of the American School Health Association for certifying schools that meet specified health standards call for an elaborate system of school tuberculin surveys.[1] The certificates given are graded from Class A through Class D and represent lessening degrees of health practices in relation to tuberculosis control carried on within the school. Some 634 schools in the state have been granted certificates to date.

BCG Vaccination

At the present BCG vaccination plays no major part in tuberculosis control in Minnesota. The views of Myers[11] prevail with health officials throughout the state. It is felt that within an area having such a low incidence of tuberculosis as does Minnesota that the effort and expense of carrying out a mass BCG vaccination program would not yield benefits comparable to cost. Again, were the major portion of the citizenry to become Mantoux positive through such a program, the use of tuberculin surveys as a valuable epidemiological tool would be lost. True, certain groups in the state, such as Mantoux negative physicians, nurses and medical students have been urged to submit to the vaccination before entering work in tuberculosis. Probably all Mantoux-negative Minnesota Indians should receive the vaccine. The epidemiological wisdom of permitting and encouraging the Mantoux-negative status within the general population must be judged at a later date.

The Role of the Physician

In the face of an almost totally absent official public health organization at county level in Minnesota, the State relies heavily upon its practicing physicians to carry out basic tuberculosis control, particularly in its case finding and case control aspects. The state health department, while prepared to give expert advice and administrative leadership and furnish certain technical aids, cannot hope to operate ubiquitously both as a field-case-finding and case-controlling agency. Since 1913[3] tuberculosis has been a reportable disease in Minnesota. This fact assures that each case first brought to light by a practicing physician will be registered at state level so that the Division of Tuberculosis can, in theory if not in practice, follow the patient's life progress even if the physician does not.

Faced with a freshly uncovered active, progressive case of tuberculosis, the physician is in a dilemma as well as is the patient. A very complex medico-social problem will now proceed to vex patient, doctor and organized society. Free laboratory facilities,[3] placed at the physician's disposal by the state, will soon inform him if the case is open and infectious. If it is so, immediate hospitalization and probably collapse therapy are indicated, in order to convert an open lesion to a closed one, protect the community and perhaps cure the patient. If the patient consents, the dilemma is solved for the doctor and the hospital or sanatorium takes over. If the patient refuses, the physician may call upon the local or state

health authorities to invoke Regulation 1503 of the state health laws and Section 144.49 of the Minnesota Statutes.[10] The former regulation states that "a person ill with tuberculosis who neglects or refuses to obey the instructions of the State Board of Health or the local health officer in matters relating to the protection of others against the disease shall be placed under quarantine in a suitable place . . . . until such time as the danger of infecting others no longer exists." This means that the tuberculous person can be forceably placed in a sanatorium, if necessary.

Occasionally, in Minnesota today, the physician will compromise and the patient will stay at home, supposedly in isolation. When this happens the physician has a constant and irritating responsibility to the community to fulfill, playing watchdog on the case. It is in this type of instance that a public health nurse often renders good service in checking on the patient at regular intervals and bringing in family and other contacts for tuberculin and x-ray screening. In general, however, the present attitude of physicians in Minnesota is that open cases of tuberculosis should go to an institution. Few patients are in Minnesota sanatoria by court order; nearly all go willingly. Exclusive of the three metropolitan areas of Minneapolis, Saint Paul and Duluth, it is estimated that there are presently only fifty open cases isolated at home in the state.[6] Public education on the benefits of sanatorium care in tuberculosis control has brought about this favorable situation.

All active cases of tuberculosis encountered in private practice involve a major change in the life of each patient, whether he stays at home or goes to an institution for care. Welfare and other social agencies are dependent on the physician for technical advice in rehabilitating him. Even inactive cases must be conscientiously followed for years by the practitioner. There is a tendency, however, for state and local health and welfare agencies to assume more and more of the technical and administrative supervision of all cases of tuberculosis in the state, with the practitioner serving as a point of reference. More and more frequently, sputums and gastric washings are examined at the state laboratories and x-rays are sent to county sanatoria to be read. It is the sanatoria who actually decide upon admission of cases, the desirability of collapse therapy, surgery, degree of healing, et cetera, and not the referring physician. The latter, realizing that the management of tuberculosis is a highly developed specialty, is usually willing to relinquish control of his cases.

The use of county sanatoria as out-patient clinics, with public health nurses as trouble shooters, is presently favored in Minnesota. It appears that the tuberculous citizen, a potential threat to the health of all, is being regarded as a ward of organized society, and eventually he will be routinely sought out and diagnosed by public health agencies as a matter of the public interest and treated essentially through public medical services.

Conflicts

Tuberculosis control in Minnesota is dominated by the State Department of Health, but several important phases of the work are under the direct supervision of other governmental agencies. The management of the tuberculous within state institutions is the responsibility of the State Department of Institutions. Thus, all criminals and insane who develop the disease remain outside of the jurisdiction of the Division of Tuberculosis. All tuberculosis sanatoria, state and county, are operated under the State Department of Welfare. Simplicity of administration and centralization of control, features usually desirable in institutional operation, would indicate the combination of these functions under the State Department of Health.

Conflicts which arise between voluntary associations, such as the National Tuberculosis Association and its state and county sub-organizations and official agencies, apparently occur only occasionally on a personality basis. At policy level, and at operating level, the voluntary agencies are at the service of the official governmental health units, ready to furnish funds, material, transportation, personnel and enthusiasm in exchange for technical and administrative leadership in a common cause.[8]

Summary

Minnesota compares very favorably with the United States as to tuberculosis mortality and is developing an effective state directed case finding program through the medium of mobile unit chest x-ray surveys. Tuberculin surveys play an important role in the case finding program but have been relegated to voluntary health agencies for realization. BCG vaccination is not favored

A SURVEY OF VALVULAR HEART DISEASE IN 1,000 CASES OF PULMONARY TUBERCULOSIS

HAROLD L. NEUENSCHWANDER, M.D., JERRY R. MILLER, M.D., and JOHN F. BRIGGS, M.D.
Saint Paul, Minnesota

THERE is a popular belief that individuals suffering from mitral stenosis are less liable to acquire pulmonary tuberculosis than other individuals; and it is believed further, that individuals with pulmonary stenosis are more susceptible to tuberculosis than other individuals. Rokitansky expressed the former view when he wrote that the chronic passive congestion of the lungs resulting from heart disease usually excludes development of tuberculosis in the lung. Following this expression is the concept that mitral stenosis protected against pulmonary tuberculosis passed on through the literature; and, even as recently as 1944, Paul White stated that pulmonary tuberculosis is rare in the presence of mitral stenosis. He further stated that chronic pulmonary congestion resulting from mitral stenosis makes it difficult for the tubercle bacillus to gain a foothold. This concept that pulmonary congestion protects against the development of tuberculosis has been refuted by workers such as Calthrop, Hawes, Buckingham and Hoffman, Bishop and Babey, Stinson, Kremer and Shapiro, Roberts, Lisa, and Kellner. In general these observers have pointed out that the incidence of mitral stenosis in people suffering from pulmonary tuberculosis is about the same as its incidence in the non-tuberculous population. It is also their opinion that pulmonary tuberculosis is not more common in individuals with pulmonary stenosis than it is in the general population at large.

We became interested in this controversy and, as a result, reviewed the incidence at autopsy of chronic valvular heart disease in 1,000 individuals in whom tuberculosis was found. These cases represent the total number of individuals who have either died or suffered from tuberculosis in a series of 10,000 necropsies performed at the Ancker Hospital by Dr. John F. Noble from 1925 to 1948. Only those individuals who were proven to have had tuberculosis at some time are included in the series. Only those patients, too, in whom valvular heart disease could be demonstrated at the autopsy table are included in the series. It was found that there was some degree of heart involvement in 17.7 per cent of the thousand cases of pulmonary tuberculosis that were reviewed to date. The mitral valve was involved in 11.1 per cent and a frank advanced mitral stenosis in 0.5 per cent. The aortic valve was involved in 9.7 per cent and the tricuspid valve in 0.7 per cent. The pulmonary valve showed a slight change in about 0.5 per cent of the cases. Of the ninety-seven patients with aortic valve defects, the greater number occurred in males; while mitral lesions predominated in females. The average age of the individuals in the survey was sixty-five years; the average age of those with aortic valve defects was sixty-eight years; and those with mitral valve lesions 62.7 years.

The chief causes of death in these 1,000 cases of pulmonary tuberculosis were: tuberculosis in 49.3 per cent and heart disease in 8.2 per cent. In the remainder, death occurred from various other illnesses. The incidence of valvular heart disease in this series of cases of 17.7 per cent compares with a reported high of 29 per cent and a low of 0.24 per cent by other authors. The relatively high figure in this series may be accounted for by the fact that it includes those cases in which acute terminal valvular endocarditis was present at the time of the autopsy. It is also recognized that the incidence of valvular heart disease is usually higher in an autopsy series of patients than in series bases on clinical diagnosis. By far the greater number of lesions involved the mitral and aortic valves; the tricuspid and pulmonary valves, as was to be expected, being seldom involved.

As regards the statement that the incidence of pulmonary tuberculosis is abnormally high in individuals with pulmonary stenosis, it is interesting to note that no true pulmonary stenotic valve defect occurred in this group. It is also interesting that the rate of occurrence of aortic valve defects is essentially the same as that reported by Doctors Clawson and Bell.

The incidence of frank mitral stenosis in our series falls well within the range of the rates

From the Departments of Medicine and Pathology, Ancker Hospital, St. Paul.

published by others for patients suffering from tuberculosis and also is about the same as that in the non-tuberculous population of this area. It is our belief that evidence is accumulating to indicate that the incidence of mitral stenosis in tuberculosis patients is about the same as in the non-tuberculous group in the same area. Because of this we feel that the old dictum that pulmonary congestion incidental to heart disease protects the patient from tuberculosis is fallacious.

Summary

The incidence of valvular heart disease at Ancker Hospital in 1,000 patients dying from or having suffered from tuberculosis is 17.7 per cent.

The aortic valve defects predominated in the male, and mitral defects predominated in the female.

Frank advanced mitral stenosis occurred in 0.5 per cent of the patients with pulmonary tuberculosis, and this incidence is essentially the same as that which occurs in this area among non-tuberculous patients.

It is recognized that the number of cases studied is statistically insignificant, but this study seems to indicate that the theory that mitral stenosis protects against pulmonary tuberculosis is probably incorrect.

The authors are indebted to Dr. John F. Noble for his suggestions and criticisms.

THE CONTROL OF TUBERCULOSIS IN MINNESOTA

(Continued from Page 377)

except for certain small, special population groups. At the present, Minnesota is well supplied with sanatoria beds (3.9 per annual death), but anticipates a need for more beds for at least a five year period during and after the mobile unit x-ray surveys of the entire population are completed. The private practitioner is still the key agent within the state for diagnosis plus treatment and follow-up of the tuberculous, but his role, eventually will probably be assumed by public health and medical services. The chief deterrents preventing official state health agencies from assuming complete control of the tuberculous are a serious lack of trained official personnel, especially public health nurses, organized at county level to carry out follow-up procedures adequately, and a lack of administrative control over certain state institutions and county sanatoria that shelter tuberculous patients.

POSITIONS OF THE PATIENT—THEIR EFFECT ON SPINAL ANESTHESIA

FRANK COLE, M.D.
Duluth, Minnesota

WHILE changes in the position of the patient are important everywhere in surgery, they are particularly so in spinal block. Incorrect positioning of the patient can mean (1) failure to produce proper anesthesia, (2) death of the patient, (3) permanent damage, (4) nerve injuries, and (5) restlessness, which may simulate unsuccessful or waning spinal block.

The effects produced by the various positions in which the patient may be placed are (1) those of gravity, in which the levels of (a) the head and feet, (b) the left and right side, or (c) the front and back may be different, and (2) those where the levels of the different parts of the body are not changed but the interrelationships of the various parts are themselves altered. The following is a list of the positions most commonly used in anesthesia and in surgery.

1. Dorsal, or supine: lying on back.
2. Dorsal recumbent: supine, legs flexed and rotated out.
3. Elliot: supine, support under small of back (for operation on the gall bladder).
4. Lateral recumbent: on side, upper thigh and knee drawn up.
5. Kraske, Depage: prone, with pelvis elevated.
6. Lithotomy, or dorsosacral: on back, legs and thighs flexed.
7. Prone: face down.
8. Sitting.
9. Trendelenburg. The Trendelenburg position is distinguished from the head down position, as it includes (1) 45 degrees of head-lowering, (2) flexion of the knees.
10. Scultetus, head-down: on inclined plane, with head down.
11. Fowler, reversed Trendelenburg: head up.
12. Unilateral: lying on side.
13. Kidney: unilateral, with lateral flexion.
14. Unusual positions, for those who cannot assume standard positions (arthritis, ankylosis, spinal injuries, previous operations).

What the surgeon wants to know:

1. What position should be used for giving the spinal anesthetic?

2. In what position should the patient be placed immediately after giving the spinal anesthetic?

3. How soon may the head be lowered?

4. What position should be used after operation?

5. How long should the patient be kept in bed?

Causes of Death from Spinal Block

Shock.—

1. White sympathetic rami theory. According to this theory, vasoconstrictor impulses are carried in the white rami of the sympathetic nervous system. These impulses stream upward into the lowest part of the cord and downward in the uppermost part, so that a block up to the upper thoracic region effectually blocks such fibers running to all parts of the body. If these fibers are blocked in performing subarachnoid nerve-root block, it is to be expected that spinal anesthesia will be associated with a fall in blood pressure and that higher levels of anesthesia will be attended by more profound lowering of the blood pressure.

2. Adrenal theory. This theory, advanced by Pitkin, asserts that the fall in blood pressure is brought about by a paralysis of adrenin secretion caused by paralysis of the sympathetic nervous system. According to this theory, spinal block up to the sixth thoracic segment paralyzes the autonomic nerves to the adrenal glands and thereby brings about a blood pressure fall.

3. Some cases are not explained by either theory.

Babcock states:

"If the lower eleven dorsal and the first three lumbar roots are completely blocked, every blood vessel in the body, from the vertex to the toes, is completely relaxed; the heart rate falls to 40, 50, or 60; no pulse may be felt at the wrist; and while there may be a soft, faint pulse in the carotids, with a completely relaxed vascular system and a partially relaxed muscular system, the blood lies in the dependent portions of the body as in a cadaver. The skin is pale, and incisions through nondependent portions of the body are dry and bloodless."

Respiratory Paralysis.—Paralysis of the intercostal muscles occurs commonly in spinal block, as it does in inhalational anesthesia. It must be remembered that the thoracic nerves which supply the skin and the muscles of the anterior abdominal wall also innervate the intercostal muscles. If skin anesthesia is desired up to the nipple line,

From the Department of Anesthesiology, St. Mary's Hospital, Duluth, Minnesota.

which would correspond to the fourth thoracic segment, motor block, which may lag some two segments behind, will surely reach as high as the sixth thoracic segment. Thus the lower six thoracic nerves on each side and the lower six intercostal muscles on either side are blocked and half of the musculature of the chest wall has been paralyzed. It is obvious, therefore, that (1) spinal block is commonly associated with some degree of respiratory depression and (2) higher levels of spinal anesthesia are associated with more severe degrees of respiratory depression. When the anesthesia has reached the first thoracic segment, all intercostal muscles are paralyzed. The patient in this situation carries on respiration with the diaphragm alone. Breathing will be of the paradoxical or negative or rocking-chair type. The chest wall, instead of rising during inspiration, will fall here and rise during expiration. Should the spinal block reach as high as the fourth cervical segment, the phrenic nerve, which is derived from the third, fourth (chiefly), and fifth cervical segments, will be paralyzed on either side, and respirations will cease.

Anatomy

The two most marked curves in the spinal column are opposite the third lumbar (anterior) and fifth thoracic (posterior) vertebrae. In the lithotomy position, the lumbar curve is obliterated. In the lateral position, the influence of the spinal curves is eliminated.

Variations in position, including those involving gravity effect and those involving alteration in interrelationships of various parts of the body, produce, in spinal block, alterations in (1) the cerebrospinal fluid, (2) circulation, (3) respirations, and bring about the following clinical effects:

Height of Anesthesia.—This is a function of the spreading cephalad of the anesthetizing solution injected. If skin anesthesia is desired up to the nipple line, corresponding to the fourth thoracic segment; and lumbar puncture is performed at the second lumbar interspace, a spread upward of ten spinal segments is required. Specific gravities of the various fluids and solutions involved are listed here for this purpose:

Cerebrospinal fluid: 1.001 to 1.009, average 1.007
Procaine, 10 per cent in water: 1.015 to 1.018
Metycaine, 10 per cent in water: 1.0145
Nupercaine, 0.5 per cent in saline: 1.0037
Pontocaine (tetracaine), 1 per cent in saline: 1.0065 to 1.0068; 0.5 per cent in saline: 1.0069
Ten per cent dextrose solutions: 1.030

Duration of Anesthesia.—For a given volume and total dose of anesthetizing solution, a higher level of anesthesia will obviously be associated with a shortened duration of anesthesia. Where a small dose (and a prolonged duration of anesthesia) is desired, for the production of a low anesthesia, the solution should be confined to the lower segments during the period immediately following its injection, to prevent it from spreading upward and from being wasted in unnecessarily anesthetizing higher nerve roots not involved in the surgical procedure contemplated.

Symmetry of Anesthesia.—If the spinal block has been performed in a unilateral position, and the patient has been kept in that position for five or ten minutes following the block, the anesthesia will be found to be asymmetrical. If the solution is heavier than spinal fluid, the level of anesthesia will be higher on the lower side; for a lighter solution, the anesthesia will be higher on the upper side.

Hypotension.—It has been shown above that, in general, higher levels of anesthesia, brought about by gravity effects produced by head-raising or head-lowering, are associated with more profound lowering of the blood pressure.

Respiratory Depression.—Depression of the respirations, as described above, is directly proportional to the spread upward through the thoracic spinal segments.

Nausea and Vomiting.—These, too, are more commonly seen in higher levels of spinal anesthesia. Hypotension associated with high anesthesia has been stated to be a cause of nausea and vomiting. Relaxation of the sphincters, often followed by the entrance of bile into the stomach, may be a factor in bringing about this complication.

Headache.—This symptom may be due to hypotension also. Leaking of the cerebrospinal fluid through the lumbar puncture is most generally asserted to be the cause of postspinal headache. The incidence of headache following spinal puncture or spinal block is fairly high and probably amounts to about 5 per cent. The headache does

not appear immediately following the puncture or block, but occurs typically when the patient sits up; it is usually severe and is relieved by lying down.

Comfort of the Patient.—It is essential, since the patient remains conscious during the entire operative procedure, that he be made as comfortable as possible. Often, during the latter part of the surgical procedure, he may become uncomfortable and markedly apprehensive. This is often interpreted as being due to a waning of the spinal block. The diagnosis can usually be made if it is noted that his pain does not correspond accurately to the surgeon's manipulations, and if the patient is unable to move his feet.

Convenience of the Surgeon (operating conditions).

The following techniques involve the use of gravity control: Barker (glucose), Babcock (heavy or light solutions), Pitkin (light solution, tiltometer), Sise (both), Labat (no vasoconstrictors), Maxson, Vehrs (gravity effect used only after fixation of drug), Jones (light, prone, to soak posterior roots), Wilson (light, sitting position), Sise (pontocaine-glucose).

Positions

Trendelenburg and Head-Down Positions.—Koster and Labat both insisted on the head-down position immediately after spinal block, to guard against cerebral anemia. Labat maintained this position for three hours after operation. Vehrs used the Trendelenburg position early but not immediately following spinal block.

Advantages: (1) it aids in bringing blood to the brain and thus insures the best possible blood supply to the vital medullary centers, (2) it aids in bringing blood from the abdomen to the heart, (3) it facilitates gravity convection. Other factors involved in spreading the solution are dispersion (mixing due to the actual injecting) and diffusion (gradual mixing, because of difference in concentrations).

Others (Grodinsky and Baker) object to the use of the head-down position as: (1) the anesthetic gravitates toward the higher centers or may simply become high; (2) the duration of anesthesia is shortened; (3) the patient is uncomfortable (this position should not be maintained too long following operation as most patients dislike it intensely); (4) the patient is in a physiologically abnormal position; (5) the respirations are embarrassed; the diaphragm and subphrenic viscera assume a more cephalad position and the patient is required to lift the weight of the abdominal viscera with each inspiratory effort; (6) it increases venous congestion in the head and neck. These workers and others use the Trendelenburg position only when there is vasomotor collapse and cerebral anemia.

Greenberg, Visscher, et al, have shown that ruminants held on their backs for over a few hours will die of pulmonary congestion, alveolar hemorrhage, and interstitial edema.[1]

When the Trendelenburg position is assumed soon after injection, the head and neck should be raised, to prevent the anesthetizing solution from affecting the higher centers. In the head-down position, the effect of gravity is not to move the drug in high concentration to the most dependent parts but to spread it out in ever-decreasing concentration over a distance proportional to the volume of drug injected.

Fowler Position.—This is a comfortable position. Slight Fowler position produces, in gallbladder or gastric surgery under spinal anesthesia, a striking falling away of the abdominal viscera from the field of operation.

Prone Position.—Breathing is difficult in this position, as it is necessary for the patient to lift a considerable part of his body weight with each inspiratory effort. Severe fall in blood pressure may be associated with the prone position, as is often shown by a return to normal on restoring the patient to a supine position. As both falls in blood pressure and respiratory depression are commonly seen when the patient has been placed in the prone position, both of these may be accentuated where spinal block, known to produce these complications of itself, has been performed.

Kraske Position.—Hypotension occurs commonly following the use of the Kraske position. It is often advantageous, for hemorrhoidectomy and for repair of rectal fissure, to employ caudal and sacral block.

Lithotomy Position.—Breathing is slightly difficult in this position, but for low rectal work this is probably superior to the Kraske position.

Lateral Position.—Breathing may be difficult in the lateral position. There is compression of the lower lung and some slight gravity resistance on inspiration. This position is used particularly where an asymmetrical or unilateral anesthesia is desired. The advantages of unilateral anesthesia are: (1) only the affected part is anesthetized, (2) a long anesthesia can be obtained, and (3) where the anesthesia is largely one-sided, there may be very little fall of blood pressure (in this regard, it may be recalled that first stage sympathectomy for hypertension is followed by no fall in blood pressure), (4) there is probably less respiratory depression where the anesthesia is largely one-sided.

Disadvantages: (1) the production of a one-sided anesthesia is uncertain, (2) somewhat more positioning is needed for this procedure, and (3) where the patient is to be operated in the supine position, he must be kept on his side for a period that is longer than usually required.

The dangers of spinal shock are its effects on the brain and heart. The warnings of cerebral anemia are: (1) rising pulse rate (the parallelism between pulse rate and blood pressure, typical of spinal block, is here broken), (2) increasing fall in blood pressure, (3) increasing pallor, and (4) possibly increased abdominal pulsations.

Injection

Sitting.—This is the easiest position for the performing of spinal block, as (1) the median plane is well defined, and (2) the pressure on the cerebrospinal fluid is greater, so that the fluid will drip freely from the needle when it has been correctly placed. When lumbar puncture is performed in the lateral position, the fluid is under very little pressure and may only ooze from the hub of the needle. The sitting position is used for low anesthesia ("sitting-bull" spinal; for work on the anus and external genitals). This position is used commonly where heavy solutions are employed. It is also used with light solutions, employing the Wilson technique. When spinal block is performed in the sitting position, it is of distinct advantage to put the patient's feet on a stool.

Lateral.—This position can be used for either light or heavy solutions. The patient is placed on his side when a high level of anesthesia is to be obtained. In this position the median crease sags and it is necessary to determine the location of the needle point in three dimensions. The anesthetist will need to find the median plane in addition to directing the point of needle cephalad or caudad. In this position, as has been mentioned above, the cerebrospinal fluid pressure is low. If the patient is to be operated on in the lateral position, the affected side is up, a light solution is used, and the patient is not turned after spinal block has been performed; or the affected side may be kept down and a heavy solution used and the patient turned to the other side when the anesthetic level is high enough. If the operation is to be done with the patient on his back, the affected side is down for heavy solutions, up for light. It will be found helpful, particularly where there is considerable sag in the median crease, to place a pillow under the lower back, so as to straighten out the spinal column.

General.—No wrestling holds should be used, as they tend only to increase the tonus of the skeletal muscles. The patient should be instructed, whether in the lateral or sitting position, to attempt to bring his nose and his knees together.

After injection, one should wait five to ten minutes before turning the patient.

Heavy Solution.—(1)For low anesthesia, the patient is kept in a sitting position for at least two minutes. (2) For anesthesia to the umbilicus, the table is kept flat for ten minutes, then the head may be lowered. (3) For anesthesia to the costal margin, the head-down position at 10 to 15 degrees is maintained until the anesthesia is high enough; a level position is then maintained for ten minutes, then Trendelenburg position if desired.

Light Solution.—(1) For low anesthesia: lateral or flat position, then Trendelenburg. (2) For anesthesia to the umbilicus, flat position, very slight head lowering. (3) For anesthesia to the ribs: 10 to 15 degrees Fowler position until high enough, then flat for ten minutes.

Isobaric Solution.—Theoretically, any position may be used. The effects are uncertain, as the solution may actually be heavier or lighter than the patient's spinal fluid. Isobaricity is probably not desirable, as the anesthetizing solution cannot be made to spread far. Isobaricity probably is of no advantage even though the claim made for it be true. A distinct danger may be presented, as a

(Continued on Page 389)

ADVANTAGES OF A SEPARATE NURSERY FOR PREMATURE INFANTS

STUART LANE AREY, M.D., and MARY P. CHRISTIANSEN, M.D.

Minneapolis, Minnesota

ANY LIVE-BORN child weighing less than 2,500 grams is considered premature, regardless of the period of gestation. All live-born premature infants should be included in this group; evidence of life being heart beat or breathing.[7]

Prematurity takes a higher toll of infant life than any other pediatric condition and is one of the ten leading causes of death. It caused 33,120 infant deaths during 1944. It is given as the cause of death in 47 per cent of all neo-natal cases. According to Potter, it is the direct cause of 25 per cent of all deaths under one year of age and is a contributing factor in another 25 per cent.[5]

Why is prematurity itself a cause of death? The immediate reason is the inability of the premature organism to support life. The lung of the premature may not be able to carry on adequate oxygen exchange for survival. The nearer the infant is to term, the larger is the capillary bed in contact with the alveolar lumen. The fetal alveoli are lined with cuboidal epithelium and, as the fetus grows, the capillaries push between the cells so that they are in contact with the alveolar spaces. If the capillary bed is inadequate, the fetus cannot survive.

	Mortality	87%	62%	43%	22%	11%	27 %

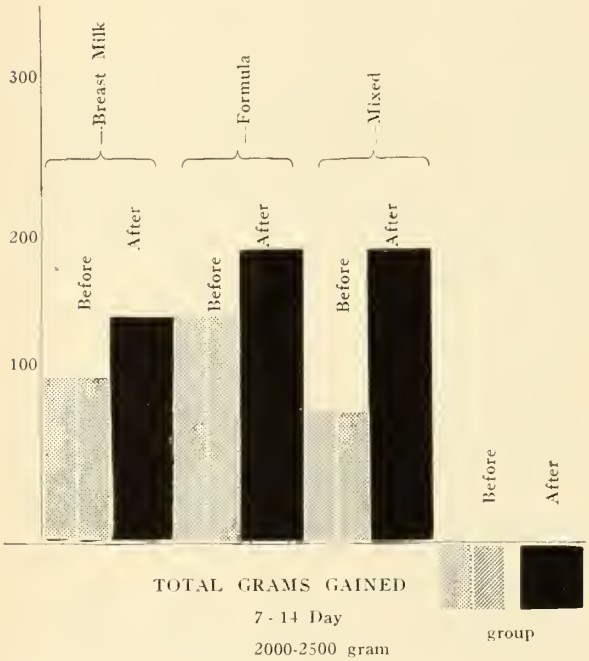

Fig. 1. Amount gained between seventh and fourteenth days in infants on breast milk, artificial food and mixed feedings.

A second factor in premature mortality is the incomplete development of the kidneys. The glomerular development continues until the thirty-sixth week of intrauterine life. Tublar development is incomplete at term.

The gastro-intestinal tract of a premature is less able to digest food than is that of the full-term infant. The digestive glands are smaller and fewer in number, but, on the whole, the digestive system is relatively more mature than either the lung or kidney.[6]

Flax[3] gives the causes of death as shown in Table II.

TABLE II. CAUSES OF DEATH

Dr. Arey is with the Department of Pediatrics, St. Barnabas Hospital, Minneapolis, and Dr. Christiansen is a Teaching Fellow, Department of Pediatrics, University of Minnesota, Minneapolis.

TABLE III. DURATION OF HOSPITAL STAY BEFORE AND AFTER ESTABLISHMENT OF SEPARATE NURSERY.

		Below 1000	1000-1250	1250-1500	1500-2000	2000--2500
Before	Cases	0	2	1	19	38
	Days	—	43	41	36.3	18.9
After	Cases	1	1	10	46	85
	Days	74	76	53.9	32.3	21

Dunham[6] groups the causes as:

1. Prematurity, especially in the low birth weight group.
2. Infection.
3. Intracranial hemorrhage.
4. Congenital defects.

In the first forty-eight hours of life, the main causes of death are asphyxia, atelectasis, and intracranial hemorrhage. After this time, the chief cause is acute infection, especially bronchopneumonia.

TABLE IV. MORBIDITY FIGURES BEFORE AND AFTER ESTABLISHMENT OF SEPARATE NURSERY.

No. Cases Before	No. Cases After	Diseases
1	—	G. C. Ophthalmitis
1	—	Pemphigus Neonatorum
1	6	Upper Respiratory Infection
—	6	Diarrhea
—	2	Pneumonia
—	1	Atelectasis

TABLE V. CAUSES OF DEATH BEFORE AND AFTER ESTABLISHMENT OF SEPARATE NURSERY.

	Prematurity	Atelectasis	Broncho-pneumonia	Intracranial Hemorrhage	Congenital Anomalies	Diarrhea	Maternal Complications	Intra-abdominal Hemorrhage
Before	33	11	1	5	2	0	5	1
After	31	5	3	2	4	2	7	0

Arey[1] was able to demonstrate an adequate cause of death in twenty-one of twenty-two consecutive autopsies on prematures.

There are two approaches in attacking the problem of prematurity; first, the prevention of premature births; and second, improved methods of caring for the infant born before term. In this paper, we are concerned only with the second group of factors.

Flax[3] attributes a reduction of premature mortality at Charity Hospital, New Orleans, to the following factors:

1. Segregation of prematures from the general nursery.
2. Care by graduate nurses.
3. Use of breast milk for all infants under three pounds.
4. Use of oxygen routinely.
5. Close co-operation between the obstetrical and pediatric groups.

At St. Barnabas Hospital, Minneapolis, from January, 1940, through October, 1947, there were 10,669 deliveries with 272, or 2.5 per cent premature births.

In the early part of 1945, a separate premature nursery was established. This consisted of two rooms with an adjoining utility room; one room for clean and one for isolation cases. This set-up was entirely separate from the newborn nursery, being on another floor. It was manned by a separate staff. A graduate nurse was on duty twenty-four hours daily. Prior to this time, the prematures were cared for in the newborn nursery. These infants were supervised by the general medical staff of the hospital, the larger group being cared for by men engaged in general practice. There was no attempt to follow a standardized routine, each man using his own methods.

Before the nursery opened there were 99 prematures with a mortality of 34.3 per cent. From February, 1945, through October, 1947, there were 176 premature infants born with a mortality of 17.6 per cent, or about a 50 per cent reduction in mortality. When these figures are broken down into standard weight groups, we find that the majority of improvement has come in the weight groups from 1,250-2,500 grams.

Hess' figures are given for comparison (Table I).

An attempt was made to determine any advantage in feeding breast milk or any special type of artificial feeding. No significant difference could be noted. There was, however, a great increase in rate of gain when the prematures were cared for in a separate nursery (Fig. 1).

The hospital stay before and after the establishment of the nursery was compared. There was no apparent advantage noted (Table III).

TRACTOR DRIVERS' COMPLAINTS

ELMER C. PAULSON, M.D.
Minneapolis, Minnesota

TECHNOLOGICAL developments in recent decades have added to the repertoire of medical syndromes. Among the more notable are caisson disease, aerotitis and aerosinusitis, asbestosis, and so on.

During several years of rural practice, the writer observed that even so innocuous-appearing an activity as driving a farm tractor can produce distressing symptoms. The most common was lower backache, or "tractor back," as it is called in some localities. From this rather obvious sequel, the gamut of complaints ranged through neck stiffness and extremity pain, to digestive upsets, frequent stools, heartburn, urinary frequency, and dizziness. Some of these were not easily traceable to tractor-driving. In fact, the writer was put to considerable effort on several occasions before he was able to exclude other maladies, and, upon eliciting a history of long hours on the tractor, assure himself of the correct diagnosis. Additional proof was obtained when the symptoms promptly subsided with cessation of tractor work. In a few cases it was deemed necessary to x-ray the gastrointestinal and even the genitourinary tracts, to exclude organic lesions.

Mechanism of Injury

The complaints occurred primarily during the seasons of "heavy" tractor work, like plowing and discing, and when the ground was hard and rough. In the spring, the farmers suddenly change from the comparative inactivity of winter to the hustle and bustle of preparing the fields. Their muscles are temporarily unaccustomed to the punishment they must undergo. The tractor lurches to and fro and from side to side in a modified version of a bucking broncho. Overambitious farmers, aware that their machines never require rest, drive themselves through long days of twelve to eighteen hours. Even the hardiest bodies cannot withstand this kind of strain for long.

The average tractor is equipped with a simple molded steel seat, shaped like the scoop of a grain shovel. This seat is attached to the tractor frame by a single-leaf steel bar-spring, which permits only limited flexibility. These seats are notoriously uncomfortable. Many a farmer has discarded this standard seat and equipped his tractor with a "hydraulic seat." To my knowledge, only one tractor manufacturer is featuring this type of seat as standard equipment.* Several farmers have informed me that the "hydraulic seat" helps eliminate the violent up-and-down bumps, but does nothing to the side-to-side lurches which are even more troublesome. So far, tractors have not had "knee-action" wheels. However, a certain tractor manufacturer† has recently come out with "knee-action" front wheels, which will certainly absorb some of these lurches, although the major side-to side lurches undoubtedly come from the rear wheels. Most farmers have discovered their own method of minimizing the bumps. They stand on the tractor chassis with slightly flexed knees, through which the shocks are absorbed.

The patients interviewed agreed readily that their speed, especially over rough ground, contributed directly to their symptoms. Rubber tires, make of tractor, age, height and weight of the driver, bore no relationship to complaints. Apparently the whole process is one of violent continuous twisting and straining of the back muscles and ligaments, with concussion of the abdominal viscera in certain cases. This concussion seems the most likely explanation for the loss of appetite, digestive upsets, epigastric soreness, flatulence, and diarrhea mentioned in Table I. Sometimes the abdominal muscles will actually be tender to the examiner's touch. The sore stiff neck which some patients complained of was due to twisting around frequently, to observe the plow or other implement being pulled by the tractor.

Treatment

The "hydraulic" tractor seat is partially successful in easing the shocks and jars of tractor driving. If the interest of agricultural manufacturers could be aroused, it might be possible through research to develop a seat which would eliminate all the bumps and lurches. It seems to me that this would be the ideal solution of the problem. In the meantime, the following measures are useful in preventing symptoms.

1. Shorter work periods on the tractor, especially at the beginning of spring work.

*Massey-Harris Company, Racine, Wisconsin.
†John Deere Farm Equipment Company, Waterloo, Iowa.

TABLE I.

Patient	Age	Weight	Height	Make of Tractors	Type of Seat	Symptoms
R. M.	23	140	5'8"	Allis Chalmers	Spring bar Later hydraulic	Abdomen shaken up. Digestive upset. Anorexia
P. F.	50	158	5'8"	Farmall	Hydraulic	Lower backache. Stiffness
F. E.	55	180	5'10"	Farmall	Spring bar	Dizziness. Pain in right arm and leg
C. L.	38	165	6'3"	Allis Chalmers	Spring bar Later hydraulic	Soreness in epigastrium. Gastrointestinal x-rays negative
H. H.	39	165	5'9"	Allis Chalmers	Spring bar	Low backache
H. D.	30	173	5'11"	Oliver	Coil spring	Stomach shaken up. Slight backache
L. W.	43	162	6'1"	McCormick Deering	Coil spring	Low backache. Pain in right flank. Urinary frequency. Kidney x-rays negative
H. K.	38	175	6'	John Deere	Spring bar	Lower backache. Stiffness
H. F.	67	130	5'6"	Farmall	Spring bar	Pain in small epigastric hernia
E. C.	36	170	5'8"	Allis Chalmers & Farmall	Hydraulic Spring bar	Stomach shaken up. Flatulence
S. W.	41	212	5'11"	Mpls. Moline	Spring bar	Sore stomach
M. J.	33	165	6'	Farmall	Hydraulic	Stomach cramps and frequent stools
H. N.	56	191	5'11"	John Deere	Spring bar	Severe low backache
O. L.	46	135	5'8"	McCormick Deering	Spring bar Later hydraulic	Pain left side abdomen. Better after hydraulic seat
J. W.	48	155	5'8"	Farmall	Spring bar	Pain in hips. Pain and stiffness in neck
L. C. Jr.	20	135	5'8"	John Deere & Farmall	Spring bar Spring bar	Backache. Headache
R. B.	28	135	5'10"	Caterpillar	Coil spring	Stiff neck. Stomach cramps. Gastrointestinal x-rays negative
L. C. Sr.	46	145	5'9"	John Deere & Farmall	Spring bar Spring bar	Low backache
P. K.	48	160	5'6"	Allis Chalmers	Spring bar	Aching arms. Stiffness and pain in neck
M. N.	31	200	6'1"	Farmall	Hydraulic	Heartburn. Stomach shaken up. Gastrointestinal x-rays negative
S. P.	66	175	5'8"	Farmall	Spring bar	Severe pain, soreness across upper abdomen
H. F.	43	175	5'11"	John Deere	Spring bar	Low backache
B. B.	21	150	5'10"	Farmall	Spring bar	Heartburn. Stomach pain

TABLE II. COMPLAINTS IN 23 PATIENTS

Complaint	No. of times Encountered
Backache	10
Indigestion (heartburn, vomiting, anorexia, cramps, loose stools)	7
Abdominal soreness	5
Sore, stiff neck	3
Pain in extremities	2
Other symptoms (headache; dizziness; urinary freq.)	3

2. Reduced speed over rough ground.

3. Standing on the tractor chassis, with knees slightly flexed, to absorb shock.

4. Abdominal and/or back supports for selected cases.

The treatment of symptoms is on an empirical basis. Cessation of driving for indefinite periods is, of course, of prior importance.

Summary

An enumeration of the symptoms suffered by a small group of farmers directly attributable to tractor-driving is made. The mechanism of production of these symptoms is discussed, as is their prevention and treatment. The most important point is recognition of the more unusual manifestation of this condition, so that correct advice and treatment will be instituted.

ADVANTAGES OF A SEPARATE NURSERY FOR PREMATURE INFANTS

(Continued from Page 385)

Morbidity—Statistics seem to favor the series before the separate nursery was established, but a check of the records before 1945 would indicate that the difference was probably due to more adequate records since opening the separate unit (Table IV).

Causes of Death—The number is not large enough to be statistically significant, but it is encouraging to note that there is still room for improvement in the theoretically preventable causes of death (Table V).

Conclusion

1. A comparison of results before and after the establishment of a separate premature nursery revealed a lowering of premature mortality by approximately one-half.

2. Care by interested graduate nurses in a separate nursery, is a most important factor in lowering the death rate among premature infants.

ST. CLOUD CANCER DETECTION CLINIC

ARTHUR H. WELLS, M.D.
Duluth, Minnesota

THE INTEREST shown in the type of Cancer Detection Clinics held in Fergus Falls over a year ago[1] and again, more recently, in St. Cloud, leads to this report of some of the reproducible details of the latter. The Stearns-Benton County Medical Society set the date of the clinic for a Saturday; decided to use a high school for the place of the examinations; limited the number of examinees to 300 adults, without specification as to status of their health; and appointed a committee of three to take care of all details. There was to be no charge and all services were to be free except for traveling expenses of five specialists who were to be brought in from the Twin Cities to help the volunteer local physicians. All unavoidable expenses were to be paid by the Minnesota Health Department and the Minnesota Branch of the American Cancer Society.

Registration

The American Legion Auxiliary was given the responsibility of registration of examinees in St. Cloud and out-lying areas. Ten phones on two phone numbers were continuously busy until the quota of 300 appointments was reached, this occurring by noon of the second day. And the phones continued ringing for the next two weeks prior to the clinic day in spite of newspaper and radio announcements that the registration was filled.

A systematic card system of the examinees was arranged according to time of appointments (9:00 A.M., 10:30 A.M., 1:00 P.M., and 3:30 P.M.) and alphabetically. Appointment cards were sent out by mail. These were later collected at the entrance of the examination center where they were exchanged for the examination forms (supplied by the Kansas State Medical Society) to be used in the clinic. The examinee's name, address and family physician's name were typed on these forms in advance. Only eight of the 300 registered cancelled their appointment and everyone came on time.

The registration had been preceded by a few days of radio and newspaper publicity which included information concerning organizations and people participating; there were advertisements supported by the druggists in each locality throughout the two counties involved.

Examination

The responsibility for different aspects of the examination was given by the medical society's committee to various women's organizations: The Stearns-Benton County Medical Auxiliary recorded the past histories of the examinees. The local registered nurses and nurses aides responded generously to help with the examinations. The St. Cloud Health Council was responsible for supplying all the lay help. Among other duties, these people directed traffic and served a light meal for the workers. A mobile x-ray unit for chest examinations was supplied by the Minnesota Health Department.

The personnel functioning in the clinic at any one time included: fourteen physicians, twenty-two graduate nurses, twelve nurses aides, and twenty-eight laywomen.

Upon presenting their appointment card at the desk near the high school entrance, examinees were given their history and examination form to carry with them through the entire examination. They were directed to the gymnasium where their past medical histories were checked through on the examination forms by eight women familiar with such procedures. From there, both men and women proceeded to have their ears, nose and throat examined by two specialists. They then separated to the dressing rooms on different floors of the school where they disrobed; women, to a dress or a cotton robe and shoes; and men to trousers and shoes. Their weights and temperatures were taken, and the remainder of the examinations of the two sexes were conducted separately.

Five screened examining tables were used for vaginal and abdominal gynecologic examinations. An equal number of physicians, nurses and recorders of findings worked together in teams of three persons. Speculae were cleaned and sterilized in xylene. The women's examination were completed in rooms with four additional tables where the breasts, heart, chest and skin were considered.

The men stopped at two places for abdominal and rectal examinations and skin, heart and chest surveys. Proctoscopic examinations were not performed unless the patient's history indicated the need.

Results

Of the 292 people examined, there were 213 females and seventy-nine males. The latter generally accompanied their wives. The examinees were responsible citizens of the community. One hundred and twenty had a positive history of cancer in the family. There were 392 surgical operations tabulated in the entire group or 130 per cent, thus averaging more than one per person examined. There was no indication of extreme neuroticism in the group. The conditions checked as positive in the histories were so numerous as to invalidate the accuracy of any summary of the reports. One hundred and sixty-six or 57 per cent were referred to their family physician for further study or treatment. Of these, fifty-five examinees required biopsies.

Of the twenty-five precancerous manifestations found, there were four kraurosis vulvae, sixteen keratosis and one each of cervical erosion, thyroid nodule, chronic hoarseness, and a mole. The twenty-four possibly cancerous lesions included eleven nodules in the breasts and either one or two cases of the following: cervical papilloma, large pelvic mass, postmenopausal discharge, cervical lymphadenopathy, rectal ulcer, rectal papilloma, melanoma of back, papilloma of inner canthus, mass in the cervix, basal cell cancer of cheek, and one ovarian cyst.

There were 177 disease processes found exclusive of the precancerous and possibly malignant conditions listed. Those of the gynecologic examination included seven cervical polyps, six cervical erosions, three cervical ulcerations, five cystoceles, four rectoceles and three cases or less of the following: leiomyomata of the uterus, enlarged uterus, pedunculated tumor of the uterus, prolapsed uterus, cervicitis, nodular cervix, vaginal discharge, trichomonas, tumor of the labia, vulva excoriations and cyst of the vulva.

It is regretted that a satisfactory follow-up has not been possible. The examinees were notified by postal card to contact their family physicians for the findings of the Cancer Detection Clinic examination. The 166 who were to have additional examinations or to be given treatment were notified twice to contact their physician. Of the 270 chest x-ray examinations, there were two suspicious of tuberculosis. No tumor masses were found.

The clinic ran smoothly throughout the day. A larger number of physicians could have been used. Fifteen to twenty chairs were necessary for people waiting for the nose and throat examination and in front of the gynecologic rooms. Otherwise, there were no delays. Most of the workers spent the entire day at their assignments.

The departing examinees were told to contact their family physician after one week for the reports. They were given small cards stating that no medical examination completely rules out the presence of cancer and that if they developed any of a series of seven specific complaints, they should immediately see their doctor.

To complete the day, an evening meeting on "Cancer" for physicians and laymen was held in the auditorium of the same school.

Summary

A one-day Cancer Detection Clinic was conducted by the Stearns-Benton County Medical Society at St. Cloud. Several organizations including the American Legion Auxiliary, registered nurses group, St. Cloud Health Council, Medical Auxiliary, Minnesota State Board of Health and the Minnesota Branch of the American Cancer Society were asked to help with specific responsibilities. There was an overwhelming demand for appointments. Fourteen physicians, twenty-two graduate nurses, twelve nurses aides and twenty-eight laywomen ran the Clinic smoothly.

Among the 213 female and seventy-nine male examinees, there was a remarkable frequency of previous surgical operations, totaling 392 procedures. One hundred and sixty-six were referred back to their family physicians for further diagnosis or treatment. Of these, fifty-five required biopsies, twenty-five had precancerous lesions and twenty-four had what might be malignancies, including eleven breast nodules.

POSITIONS OF THE PATIENT—THEIR EFFECT ON SPINAL ANESTHESIA

(Continued from Page 383)

dangerously high level of anesthesia has been known to attend the use of these solutions.

Jones Technique.—The patient is placed in the prone position and light solution used to "soak the posterior roots."

Wilson Technique.—The sitting position is used, with light solutions. A segmental type of anesthesia may be produced. If a light solution is injected with the patient in a sitting position, the solution will float upward until a sufficiently high level of anesthesia is produced and the patient is restored to a level position. It is thus possible to produce a zonal, or segmental, anesthesia with an unanesthetized area both above and below the area anesthetized; a longer anesthesia can be produced or, what is very likely the same thing, smaller doses may be employed. Possibly less shock may occur. At least in the hands of the inexpert, this is generally regarded as being a rather dangerous procedure.

After operation abrupt changes in position are to be avoided. Suddenly raising the head may cause cerebral anemia. The vasomotor system, which ordinarily adjusts itself automatically to change in posture, does not fully recover its sensitive response for hours. Therefore, if the head has been tipped down, keep it down on the way back from the operating room and on getting into bed. If the patient has been horizontal, let him stay that way. Movements should be few and gentle. Remember, in moving the patient, that he is not anesthetized above the waist.

History of Medicine In Minnesota

HISTORY OF MEDICINE IN LE SUEUR COUNTY

(Continued from March issue)

H. E. Conley, J. C. Kinkle, George Kelly, F. F. Clifford, G. W. Johnson, James Green, E. P. Whitford, a Dr. Kernan and a Dr. Jellison all opened offices in Le Sueur County. At the end of the decade came W. S. Woods, S. B. Coe and James McKeon. J. P. Williams practiced in Le Sueur from 1884 to 1886.

During these years diphtheria was prevalent in a fatal form. In the winter and spring of 1880, the vicinities of Cordova and Montgomery were afflicted, and, at Waterville, Dr. Case reported thirteen cases in one week. All through the following year there were cases reported at various places in the county. One family near New Prague lost five children, and many families lost at least one member. In November of 1882 the newspapers recorded an outbreak of fifteen cases, including five deaths, in the town of Le Sueur. Dr. Ayer, to whom the county commissioners gave full authority, suggested disinfecting the sick rooms in order to prevent further spread of the disease. In the fall of 1883 and in the fall of 1884 there were several fatal cases. After two years of freedom from the disease, Le Sueur County was struck again—the school at Kasota was closed in order to halt the spread of the disease.

The last two years of the decade also saw recurrences of diphtheria.

In 1880, cases of cholera morbus were distressingly frequent at Ottawa. The following fall there was an outcropping of typhoid fever in the lower part of the town of Le Sueur. In the spring of 1882, and again in 1883, a number of cases of scarlatina were tallied, and in 1889 there was an epidemic. May issues of newspapers reported 120 sufferers from this malady.

Cases of smallpox in Montgomery created a furor in the spring of 1882. Dr. E. J. Brown of Minneapolis gave a graphic report of the event to the State Sanitary Conference later that year, telling the conference that when he was summoned to take charge he found the pest house located about six miles from the town. When he entered, he saw that one room contained all the patients —four males and three females—ranging in age from twelve months to twenty-four years. The only attendant was their mother, exhausted and half-crazed with grief. The four older ones were in an advanced stage of the disease, and their black faces presented an almost unbroken suppurative tract. The stench and filth were terrible.

The children had been sick for nine days without a physician, medicines or proper food and with only such care as the mother could give. The throats of the older ones had become so affected by the disease that they could swallow no solid food; they had had nothing but flour gruel and alcohol.

The doctor reported that he had to get food by persuasion and threat, and he had a difficult time vaccinating people.

The local inhabitants were fearful of contracting the disease and would not furnish the physician with a horse because they did not think he should break quarantine. After a week he was allowed to take rooms in the hotel at Mont-

gomery. The baby died of neglect and starvation. A fourteen-year-old boy, who belonged to the infected family but who had not been exposed to the disease, was kept in an out-house and people were forbidden to harbor him.

One of the patients had been seen twice during the early stages of the disease by Dr. W. H. Wood; but after the diagnosis, the town would not allow the doctor to call on the man again. A telegram to Minneapolis brought no response. After the death of the patient, the county supervisors sent a man to disinfect the residence, which he did by burning clothes, furniture, kitchenware and other household equipment. Nine days later the other members of the family had become infected, and Dr. Brown was called.

Many of Dr. Brown's statements, as recounted here, were denied by Frank Becker of Montgomery,* who said that there had been no objection to vaccination, that a man was hired as a nurse for three dollars a day, that Dr. Brown had arrived two days after the family had been taken ill (instead of nine days later), and that provisions of all kinds had been furnished to him.

1890-1900

There were no serious epidemics in Le Sueur County during the nineties. In 1891, in Kasota, there were a few cases of diphtheria, and then, with the exception of a few scattered cases, the county was free from the disease until 1900, when it again appeared in the town of Le Sueur. In 1892 there were a few cases of scarlatina in Le Sueur; in 1900 there were a few in Le Sueur Center.

In 1890, Dr. George Schultz located in Elysian. In 1893, Dr. D. A. Kirk arrived in Le Sueur, where he remained for about fifteen years. In 1894, Dr. H. B. Aitkens, a recent graduate of the University of Minnesota, opened an office in Lexington. Several years later he moved to Le Sueur Center, where he was an active member of the profession. Dr. J. E. LeClerc, a member of local and state medical societies, began practicing in Le Sueur in 1896. Dr. J. F. McDonald was practicing in Kilkenny about this time. In 1890, Dr. Norman G. Parker located in Le Sueur. A number of other physicians came for very short periods.

The office of coroner was filled by Drs. Umphrey, Dolan, Aitkens and McDonald. In the town of Le Sueur, Dr. W. H. Fisher served as president of the Board of Health. F. A. Dodge and N. G. Parker were also members of the board. In Montgomery, James McKeon officiated; and in Elysian, George Schultz held the position.

In 1892, Dr. E. P. Case opened a sanitorium at Waterville. The building was situated on an elevation overlooking the lake. It was built of wood, three stories high, and had a basement 38 by 74 feet. The sanitorium featured such modern improvements as steam heat, hot and cold water, Turkish, electric and shower baths. A few years after its opening, the sanitorium was destroyed by fire; but since it was fully insured, the structure, according to historical records, was rebuilt.

Although privately built telephone lines, of short length, began to be used between house, office and drug store, it was not until some years later that telephone companies began to connect farm houses with central offices. Practically all calls for physicians came by messenger, and until 1910 or thereabouts, the doctor traveled horseback or by horse and buggy. In many localities like this one, pioneer days lasted a long time.

* *Le Sueur Sentinel*, December 28, 1882.

About 1903, the Nicollet-Le Sueur Medical Society was organized. Physicians from the western part of the county generally belonged; whereas, those living in the eastern part affiliated themselves with the Scott-Carver County Medical Society. Those from the southwest belonged to the Waseca County organization.

HISTORY OF MEDICINE IN NICOLLET COUNTY

The business of treating sick persons, in the stretch of country now known as Nicollet County, was in the hands of Indian medicine men until 1853, when Fort Ridgeley was established in the western part of the county. Consequently, the first physicians were members of the United States Army. Dr. Alexander B. Hasson, an assistant surgeon, came to the fort in 1853 and was stationed there for a few months. He was succeeded by Dr. Asa W. Daniels, a graduate of the Medical College of Ohio. After a short stay, Dr. Daniels was appointed surgeon to the Lower Sioux Agency, about twelve miles away in Redwood County. It was here, in 1853 or 1854, that an Indian with a bad gunshot wound in his arm was brought to him for treatment. The doctor judged that the arm should be amputated, so he administered chloroform and performed the operation in the presence of the man's friends. This was the first time, so far as anyone knows, that chloroform had been used in the district northwest of the Mississippi. It is said to have made a great impression on the Indians, who spread the news far and wide that there was a white doctor who could make the soul leave the body and then come back again. Months later an Indian medicine man came a distance of "many suns" to get some of this wonderful stuff; but although he offered his pony and all his other possessions, the doctor refused his request, and he returned home a much disappointed man.

The third surgeon at the fort was Roberts Barthelow, who later became a professor at Jefferson Medical School and the author of a popular text book.

The fourth physician stationed at the fort was Dr. Alfred Mueller. He was there from 1861 until 1867, when he went to New Ulm and became one of the outstanding practitioners of Brown County. Dr. Mueller was the only physician at the fort in 1862 during the memorable battle with the Indians. The fort was, at that time, filled with refugees from the surrounding country, and it is recounted that during the attack 300 women and children lay for hours flat on their faces in an outbuilding without food or water.

Dr. Mueller showed his ability and skill as a surgeon, continuing his work in the din of battle, while expecting to lose his scalp at any moment. In addition to caring for the battle casualties, Dr. Mueller officiated at the births of three children.

Mrs. Mueller, who evidently had some ability and training as a nurse, helped her husband in caring for the wounded. Charles S. Bryant, in his *History of the Minnesota Valley*, paid a glowing tribute to the doctor and his wife for the services they rendered at this time, and the Commonwealth of Minnesota erected a monument to Eliza Mueller on the site of the Indian siege.

The first physician in civil practice to locate in Nicollet County was Dr. Hiram Wesley Catlin. He came to St. Peter in 1855 and practiced there until 1861, when, as he was about to move to Ohio, he was suddenly taken ill and died. Dr. Catlin was a graduate of the Louisville Medical College and had served in the Mexican war and practiced in Indiana before coming to Minnesota. At the time of his death, his practice in St. Peter was taken over by Dr. Asa Daniels, who returned to Nicollet County to live, and who was to become one of the most

prominent physicians in the locality. He served on many local boards and later became one of the first members of the Minnesota State Board of Health. He held membership in various medical fraternities.

E. F. Clark and William F. Hunter also located in St. Peter in 1855, and, in the following year, came R. H. Ewing, a doctor named Horne and C. Robb. These men remained only for short periods of time. Ewing practiced medicine and also kept the Ewing House, but, even at that, he must have found business difficult in the pioneer settlement. In attempting to collect his bills, prior to leaving the county in 1859, he announced that "ginseng, oats or corn will be taken at their highest market value."† It is doubtful if Robb practiced medicine during his stay. One other physician, Dr. Philander P. Humphrey, located in the county in these early days. He came to St. Peter in 1857 and remained until he was appointed, at a salary of $1,000 a year, to fill Dr. Daniels' post as physician at the Lower Sioux Agency in Redwood County. He and his wife and two children were killed during the Indian outbreak of 1862.

Besides Dr. Daniels, about fourteen other physicians practiced in Nicollet County during the sixties. One of the first to come was Jared Waldo Daniels, a brother of Asa Daniels. Before his arrival in St. Peter in 1860, he had been a government physician at the Yellow Medicine Indian Agency. During the Civil War he rose to the rank of major, serving under General H. H. Sibley and General Alfred Sully. After the war he spent two years in Faribault, Rice County, and then returned to Nicollet, where he lived, off and on, for a stretch of fifteen years. During this time, he served at various Indian agencies. William B. McCullough and L. H. Bullious were also early-comers who practiced in St. Peter for short periods. C. W. Le Boutellier, a member of the Ninth Minnesota Regiment of Volunteer Infantry, was stationed in the town in 1862. These men were followed by M. Flossion, a Frenchman; J. La Dow, Calvin Pratt, Frank W. Page, Henry C. Lehnert, and Isaac Cosner. The two latter were the first homeopaths in the county. All of these men lived at St. Peter. C. Hoberg, the first physician at Traverse, practiced there from 1864 until his death ten years later. Samuel E. Shantz, the first superintendent of the State Hospital for the Insane, came in 1866 and held the position until his death from typhoid fever in August, 1868. This institution, the first of its kind in the state, was located at St. Peter by the state legislature of 1866.

The *St. Peter Tribune* for January 23, 1867, gives an idea of the size of the new institution, which had over forty patients—"as many as there is room for." Dr. Shantz' assistant was a young Canadian, Jacob E. Bowers, who had just received his diploma from the medical department of the University of Michigan. He came in the spring of 1868 and remained at the hospital until he was appointed, ten years later, superintendent of the hospital for the insane at Rochester. He served as acting superintendent at St. Peter during the five months interim between the death of Dr. Shantz and the arrival of his successor, Dr. Cyrus K. Bartlett. The latter, a graduate of the Harvard Medical School, had been in charge of an asylum in Massachusetts before coming to Minnesota. Under his administration, the old building was abandoned and the present site was occupied. New buildings were built as the number of occupants increased.

At this time there was no office of county physician. The post of coroner was filled by Isaac Cosner.

There seems to have been an unusually large amount of sickness in Nicollet County during the sixties. During the first two or three years of the decade

†*St. Peter Free Press*, September 14, 1859.

there were a few cases of measles, typhoid fever and scarlet fever. In 1863 there were several people who died on the same day that they became ill, and their deaths were attributed, according to the newspapers, to spotted fever. However, the major complaint of these years was diphtheria. There were many cases in Nicollet County and in neighboring localities. A report written by Dr. A. W. Daniels for the Minnesota State Board of Health stated, in part:

"The first epidemic of diphtheria appeared in our village during the fall of 1862, soon after the Indian outbreak. At that time the town was crowded with refugees from the surrounding country, and every house was filled to capacity. The sudden influx of so large a number of destitute, half-clad and suffering people soon produced a deplorable sanitary condition. Typhoid fever was first to make its appearance, soon followed by measles and diphtheria, the two latter becoming epidemic. I have no notes to enable me to supply an accurate number of cases and percentages of mortality and, therefore, must rely upon memory. Probably there were not less than seventy cases of diphtheria, of which some twenty were fatal. The deaths were mostly those of children under ten years of age.

"Throughout the epidemic the disease manifested a decided tendency to attack such as were suffering from measles, and a large proportion of the deaths was the result of this complication."

A newspaper item furnishes the information that between August 18, 1862, and January 23, 1863, there were 127 persons buried in the local cemetery, and that, of these, twenty were residents of the town, and sixty of the total were children. Sporadic cases occurred in the following years.

In 1862, there was, apparently, a military hospital in St. Peter and, at this time, C. W. Le Boutellier was the surgeon in charge. In the winter of 1863-64, St. Peter was the headquarters of the Sixth Regiment, under the command of Colonel Crooks. This added to the already crowded condition of the town. Living quarters were unsanitary and badly ventilated. Sewage was not properly disposed of, and the water supply, from shallow wells, soon became polluted. The result was a number of cases of measles, typhus, cerebrospinal meningitis, diphtheria and smallpox. Under these adverse conditions Dr. Alfred Wharton, surgeon of the Sixth Regiment, performed his duties, assisted by Dr. Potter. Nine deaths occurred from smallpox alone. Naturally these diseases were not confined to the soldiers, but involved the civilian population as well. In 1869, according to the *St. Peter Tribune*, there were seven cases of smallpox in the town of Bernadotte, three of which were fatal.

1870-1879

M. W. Scott practiced medicine in St. Peter for a short time in 1870, and C. A. McCohlon and J. R. Nelson were there for brief periods in 1871. Two other physicians came about this time, both of whom were to practice in the county for many years and to become well known in their profession. They were Daniel B. Collins and George F. Merritt. The former located in St. Peter shortly after receiving his diploma from Rush Medical College. With the exception of two years, he continued to live in St. Peter until his death in 1898. He was several times elected health officer and city physician, and he served as surgeon for the Second Regiment of the Minnesota National Guard. He belonged to many organizations, and when the local and state medical fraternities were organized, he joined. Dr. Merritt, also a graduate of Rush, practiced in St. Peter until his death in 1921. He was also a member of various fraternal orders and the local, state and national medical societies.

Dr. John Pehrsoon shared the office of Dr. A. W. Daniels for a year or so. He later became a lecturer at the College of Physicians and Surgeons in Min-

neapolis. Dr. J. H. James spent the years 1876 to 1891 in St. Peter, and besides his duties as assistant physician at the hospital for the insane, he often attended patients in the town and the surrounding country.

Marion Putnam, about whom very little is known, was in St. Peter in 1878. In the same year came Dr. V. Bolon, a German who specialized in eye and ear work, but who probably made more money as a *geburts-helfer.*

In all, there were at least nine regular physicians and one homeopath who were well established in the county by the end of the seventies. All were located in St. Peter.

The Minnesota State Medical association, reorganized in 1869, elected a number of Nicollet County physicians to membership during the seventies. Dr. A. W. Daniels was a charter member. Dr. C. K. Bartlett, elected in 1870, wrote the semi-annual essay in 1872 on the subject of insanity and its treatment. Dr. J. E. Bowers, also of the St. Peter asylum, was elected in 1870. Later members were John Pehrsoon, J. H. James and G. F. Merritt.

Dr. A. W. Daniels was a member of the Blue Earth Medical Society, which changed its name in 1872 to the Minnesota Southwestern Medical Society.

In 1870, typhoid fever was reported to be quite prevalent in the vicinity of St. Peter. In November, Dr. Daniels reported that he had twelve cases under his care. In the same year there were rumors of many cases of smallpox. The newspapers insisted, however, that aside from a few cases at the hospital, there had been only three cases of varioloid and one mild case of smallpox in the town. Several persons living four or five miles from town were reported infected in 1872, but apparently the disease did not spread outside of one family circle.

It was said in the spring of 1875 that "mumps were spread all over town" and that eight persons suffering from the disease were staying at the Nicollet House. In the spring of the following year several small children in St. Peter were reported dead of whooping cough. There were always a few cases of typhoid fever, and scarlet fever was prevalent in a mild form, during 1875 and 1876. A few cases of diphtheria appeared every year. In 1875, 1878 and 1879, they became more numerous and more often fatal.

Dr. A. W. Daniels, in his report to the State Board of Health in 1878, reported the epidemic as follows:

"The present epidemic of diphtheria commenced early in September and has not yet fully disappeared. It was noticed that the disease did not effect a lodgement in a particular part of town and spread from that infected district, but appeared in different localities about the same time, and the first victims were children whose tender years had necessarily confined them to their homes.

"The number of cases, as near as can be ascertained from careful inquiry among the physicians, has somewhat exceeded 100. Of these, fourteen fatal cases are reported. But few adults have been attacked, and none have died. Children have been the principal sufferers, and the fatal cases are generally under eight years of age.

"The catarrhal has been the prevailing variety. But this form of the disease has manifested a marked tendency to extend itself to the air passages and to assume the croupal variety. From this complication has come the great mortality of the disease. Every death during the present epidemic has been the result of croupous diphtheria—nineteen cases have occurred, with only five recoveries.

"A large proportion of the fatal cases received little or no treatment. Parents, supposing their children were 'only suffering from a cold,' neglected calling a physician until it was too late to prevent a fatal result."**

**Written in 1878. Published in the Minnesota State Board of Health *Reports* for 1879.

Courtland was the scene of the epidemic of 1879. The disease, apparently imported from Mankato, began in the spring. There were three fatal cases in the first family infected. It then spread over almost the entire township. It was noticeable that in the western part of Courtland, where the drainage was good and the living conditions more sanitary, that there were fewer fatal cases than in the eastern part where the drainage was very poor. During the year the total number of deaths from all causes was 188. Of these, twenty-one were caused by diphtheria.

During the seventies, Isaac Cosner often filled the office of county coroner, and A. W. Daniels and G. F. Merritt, the office of county physician.

1880-1889

E. C. Putnam, probably the first regular physician in the town of Nicollet, came in 1881 and remained there for about a year and a half. A. Keller also located there at about the same date. He remained an even shorter time. Joseph Wicke enjoyed a good practice in Nicollet from 1887 until his death in 1895. He also ran a drug store and served as president of the village council.

W. A. Jones, a native of Nicollet County, served as intern at the state hospital in 1881 and 1882. He later practiced in Minneapolis and was appointed as lecturer on nervous diseases at the University. He was for many years editor of the *Journal Lancet* and a member of the State Board of Health.

Another newcomer was George W. McIntyre, who practiced in St. Peter from 1883 until his death in 1920. During this period, he served for several years as assistant physician at the state hospital.

Arthur F. Kilbourne was also an assistant there from 1884 until 1889 when he was appointed superintendent of the hospital for the insane at Rochester. In 1889, C. M. Skinner located in St. Peter, where he built up a large practice. C. Kranz also practiced in Nicollet County during the eighties and nineties. He held an exemption certificate.

In 1881, when the Minnesota Valley Medical Society was organized in Le Sueur, several Nicollet County physicians were present. A. W. Daniels was elected second vice president, and G. F. Merritt, treasurer, an office which he held almost continuously until 1910. He was also treasurer of the Southern Minnesota Medical Society after the two organizations merged in 1913. Other Nicollet County members elected during these years were W. A. Jones, C. K. Bartlett, who served as president in 1882, D. B. Collins, G. W. McIntyre and J. H. James. The latter was also elected to membership in the Minnesota State Medical Society.

The effect of organizing may be seen in an agreement between Drs. Daniels, Collins and Merritt, who published a notice in 1884 to the effect that all calls made between the hours of 9 p.m. and 5 a.m. would be charged at double the usual rates.

Physicians may have complained of not being paid, but they could scarcely complain of not having enough work to keep them busy. During the eighties, diphtheria was prevalent in a fatal form almost every year. It was particularly bad in the early years of the decade and, in 1880, there were far more deaths than the county had ever known. It broke out in Courtland and Lafayette in May. The latter town had fifteen deaths from the disease within that one month.

At one period in June, Dr. Collins reported that he was attending twenty-seven cases in the town of Bernadotte. There were also many cases in New Sweden, Lake Prairie and St. Peter. It was not at all unusual for families to lose three or four children within a few weeks. Many families lost all their children. The

worst part of the epidemic seems to have been over by the end of June, although there were a number of fatal cases during the following months.

The total number of deaths from all causes in 1880 was 289. Of these, 115 (including the fifty-eight in the State Hospital for the Insane) were caused by diphtheria. In 1881 there were fifty-seven deaths from diphtheria. A few occurred in almost every month of the year, and they were distributed pretty well over the county, although Lafayette and Lake Prairie led with fourteen and thirteen cases, respectively. Most of them were children.

In 1882, the total number of fatal cases was eighteen. Statistics for the next four years are lacking, and it would seem that there were fewer cases and considerably fewer deaths. In 1887 there were twenty fatal cases. In 1889 there were also quite a few. Not merely Nicollet County but the whole state suffered during these years. It is appalling today to think that any epidemic could continue so long and extend over such a wide area.

Second on the list of contagious diseases was scarlet fever. It was most prevalent in the last two years of the decade, but, fortunately, it was mild in form. From June, 1887, to 1888, there were twenty-three cases, with four deaths, in St. Peter. From June, 1888, to June, 1889, there were thirty, including only one death. Other diseases, chiefly consumption, typhoid, measles and whooping cough, affected the population, but usually the epidemics were mild in form and there were few deaths.

In St. Peter a local board of health took measures to protect the citizens of the town. School children were vaccinated for smallpox, and in 1881 a set of rules was inaugurated which insisted on the reporting and quarantining of contagious and infectious diseases and prohibited public funerals for such cases. In 1885 a notice was published that all owners of property in the city should clean up their premises. A public dumping ground was designated. In 1889, steps were taken to improve the city water supply. Drs. McIntyre, Collins and Merritt served on the board of health.

There seems to have been no office of county physician during these years, since all the well-established physicians in the county, and some from outside the county, sent in bills to the county commissioners for medical services rendered. Sometimes the county poor were sent to hospitals in neighboring counties for medical care because Nicollet County had no such facilities.

Among the interesting operations performed by local men at this time were those for cataract done by Dr. J. H. James, who was one of the first eye specialists outside the Twin Cities.

(To be continued in the May issue.)

President's Letter

WE CAN'T STOP NOW

The American doctor never finishes his education. His M.D. degree is only the entrance requirement to the larger school of medical practice. At no point can he stop and reflect that a complete grasp of medical science is his; for the discoveries and developments in this field never stop. Often we doctors feel as frustrated as a man running up a downward-bound escalator when we visualize the literally endless vista of steps to be taken in the direction of increased knowledge and skill.

And there is never time enough.

Not time enough to read all the medical journals, observe all the techniques of our colleagues, enroll in all the refresher courses, study all the important case histories. No matter how many hours we slice from our already limited leisure time, there is never time enough to do the study and research we'd like.

That is why the annual meeting of the Minnesota State Medical Association is so valuable. Here, in a fact-packed three days, we can gain the results of hundreds of hours of analysis and condensation.

In essence, it is like the arrangement the late Joseph Pullitzer had for news coverage. He hired a staff of journalists to do nothing but read through the news, weigh and compare and sift out the trivia. The finished product was a concise, comprehensive survey of the day's events and took him only a few minutes to peruse.

As always, the annual meeting has a careful balance of lectures and clinico-pathological sessions. The subjects have been selected by the Committee on Scientific Assembly after long consideration and comparison of values.

I believe we approach this convention with a deeper appreciation than we have in former years. In view of the many critical thrusts at the economic and scientific principles of medical practice, we have an even greater responsibility to enhance our value as doctors and citizens.

President, Minnesota State Medical Association

Editorial

CARL B. DRAKE, M.D., *Editor;* GEORGE EARL, M.D., HENRY L. ULRICH, M.D., *Associate Editors*

GOVERNMENT MEDICAL CARE IN ACTION

BEFORE making any radical change in the provision of medical care such as the Wagner-Murray-Dingell Bill provides, or even advocating the change to government provision medical care, it would be well to understand how it works. European countries have had government medicine of various types for many years, and can be cited as illustrative of its functioning.

In England the panel system was inaugurated in 1912 and applied to a third of the population. During World War II, it expanded to include half the population. This was a limited medical service providing only for the services of the general practitioner in the office and at home. On July 5, 1948, all types of medical service were included and, although this new experiment has been in effect but a short time, government medicine itself is not new in England, and an evaluation of its operation today is possible.

Impressions of the status of medical practice in England today have been recorded by Dr. William H. Sweet* of Boston after a recent period of practice there which culminated a number of years' residence and an intermittent practice in England. The picture he paints of the present quality of medical practice and the lot of the medical profession under the socialistic regime is illuminating.

The panel system continues, and general practitioners are swamped by patients with petty complaints and an apparently increased number of neurotics. Certificates for sick leave, extra food and even hot water bottles occupy much of the practitioner's time. Those with a panel of 2,000 see, on the average, fifty patients a day; and those with a panel of 4,000, as high as 100 a day. One can imagine that ordinary history taking and physical examination of so many individuals is an impossibility. Although there is one doctor for every 875 inhabitants in England, the panels are larger than this number, as individuals are assigned to the general practitioners only. The easiest way to get off work is by means of a doctor's certificate, and if the doctor doesn't readily comply, the individual joins another panel. X-ray service, for the most part, is limited to the hospitals, and this type of service is swamped with the needs of hospital cases. As a result, the general practitioners, as a rule, cannot follow an interesting diagnostic case to any extent, but must refer the patient to the specialist in the hospital. House calls day or night being free, a practitioner can easily be worn out, if he is conscientious, by midnight calls, which he dare not refuse, in case he might overlook an emergency. Orthopedic appliances and eyeglasses, being free, are overprescribed. Further, it is attested, a manufacturer, if not in government favor, may easily be driven out of business.

The author tells of one outstanding specialist who anticipated great things from government medicine but has been greatly disappointed, inasmuch as his new institute, which should have been completed in four months, has not been completed after four years due to government red tape—the requirements for a permit for every item of material, transportation, type of labor, ad infinitum. The author tells of requesting a special kind of instrument from the University of Health. After eight months, the request was refused because the instrument was of an unusual type. Long before that he had purchased one from a private source.

Salary compensation for specialists (in England, known as consultants) has not yet been settled, but the average compensation is about $2,500 net after taxes; and this for one who has spent fifteen years in study and practice. The mechanic in England is better compensated!

The British Medical Association was not consulted when the medical profession was taken over by the labor government. The author believes that the profession made a mistake in not analyzing the defects of the proposed system and proposing in its stead a well-conceived plan of improvement, taking a stand against the ill-advised government changes. The profession in

*Sweet, William H.: Recent impressions of medical practice in Great Britain. *New England Journal of Medicine,* 240:168, (Feb. 3) 1949.

America might well profit from the experience of our British confrères.

The author makes a clear analysis of the disadvantages of any system of medical care which changes the incentive of the patient, making the physician, rather than the individual, responsible for his client's health. When convalescence is paid for by others it is bound to be protracted. Subjective symptoms are always difficult for the physician to evaluate, and the addition of certain factors inherent in government care of sickness makes differentiation of serious organic illness from functional or simulated complaints well nigh impossible. When it is advantageous for individuals to present themselves to a doctor with medical complaints, more will do so.

The author pointedly concludes:

"If the task of assessing the ability to lead an active life and the compensability of lack of enthusiasm therefore is to be extended to the entire population, the experience in Great Britain suggests that in this country extended ill feeling between the medical profession and other segments of the nation and a deterioration in the quality of medical care can be anticipated."

THE ARTHRITIS AND RHEUMATISM FOUNDATION

EFFECTIVE attack on crippling rheumatic diseases will require the raising of at least $6,100,000 for research alone over the next five years. This recommendation was made recently to The Arthritis and Rheumatism Foundation by a National Research Council Committee appointed to survey research needs in this field.

Rheumatic disease, the committee's report stated, "is the most common cause of chronic illness." It pointed out that "approximately 7,500,000 Americans have arthritis or some other form of rheumatic disease."

"The magnitude of this problem is great," the committee declared, "as manifest by the incidence of the diseases and by the many related social and economic problems. The rheumatic disease group, although one of the oldest known to medical history, is one of the most neglected fields of medicine."

The need for research, it was pointed out, is shown by the fact that, except for conditions directly traceable to infections, the causes of rheumatic disease are still unknown, and present treatments, though helpful, include no specific cure.

Seventeen distinguished physicians and scientists, under the chairmanship of Dr. Walter Bauer of Harvard Medical School, participated in the survey report. The five-year program they recommended calls for $4,300,000 for support of researches, and $1,800,000 in research fellowships to train able young investigators, and thus to overcome a deficiency in the number of competent research workers in the field of arthritis and other rheumatisms.

The other members of this committee are: Dr. Franz Alexander of University of Illinois; Dr. Granville A. Bennett of University of Illinois; Dr. William Bloom of University of Chicago; Dr. Robert Elman of Washington University; Dr. Richard H. Freyberg of Cornell University; Dr. Ralph W. Gerard of University of Chicago; Dr. Philip S. Hench of Mayo Foundation; Dr. C. N. H. Long of Yale University; Dr. Colin M. MacLeod of New York University; Dr. Karl Meyer of Columbia University; Dr. Charles Ragan of Columbia University; Dr. William D. Robinson of University of Michigan; Dr. Edward S. Rogers of University of California; Dr. Howard A. Rusk of New York University; Dr. Francis O. Schmitt of Massachusetts Institute of Technology; and Dr. T. C. Thompson of Columbia University.

All the rheumatic diseases have one thing in common, the report stated. The portions of the body which they attack—the bone, cartilage, muscle and connective tissue—all develop from what is called "embryonic mesenchymal tissue."

"It is essential," the report declared, "that information regarding this significant tissue be increased as rapidly as possible to afford basic data needed for elucidation of the over-all problem."

Two other broad fields of research which the committee said should be developed were the specific clinical and physiological problems of arthritis and other rheumatic diseases, and the social, environmental and other public health factors bearing on these diseases.

The committee indicated many specific research leads which should be investigated thoroughly. Rheumatoid arthritis, the worst of the cripplers, tends to wholly or partially disappear during pregnancy and during severe attacks of jaundice, thus indicating, according to members of the committee, that a specific cure for this disease can be found.

The fact that some forms of rheumatic disease, such as rheumatoid arthritis, more often attack women, while others such as rheumatoid spondylitis or "poker spine" chiefly attack men, was cited as the example of the need for research on the sex hormones and other ductless gland products in relation to rheumatic disease.

Other projects recommended to The Arthritis and Rheumatism Foundation included:

The relation of germ and virus infection to the onset of rheumatoid arthritis and of rheumatic fever, which by bringing on heart disease kills more children between the ages of five and nineteen than any other illness.

Studies of the blood and circulatory system aimed at checking osteo-arthritis, the rheumatism of old people, together with aging and other degenerative changes.

Hereditary factors in relation to all rheumatic diseases, including gout.

Emotional factors related to the development and persistence of arthritis.

In the attack on the rheumatic diseases, it was recommended that research be carried down to the basic molecules of tissues involved. For this, it was said "it is necessary to enlist the cooperative efforts of physicists, chemists, biologists and medical scientists." It was declared that new technique, such as the use of radio-active tracer substances and other new scientific techniques should be used.

"Much may be accomplished by electron microscopy," the report declared. "Application of biophysical techniques, x-ray diffraction, ultraviolet, polarization, phase-contrast, and dark-field microscopy also deserve encouragement, and may provide a clearer understanding of the normal as well as abnormal structure."

The Arthritis and Rheumatism Foundation, for which the report was prepared, has its offices at 535 Fifth Avenue, New York City. It was organized by Floyd B. Odlum, who is chairman of its board, and a group of lay and medical leaders throughout the nation. It is now trying to raise $2,000,000 for its first-year program.

Half of this money is to go to the Foundation for the purpose of financing a nation-wide research program and conducting a campaign of public education concerning what can be done about these crippling afflictions.

The other half will be retained locally to help provide better means of treatment. The Minnesota-Dakota Chapter of the Foundation is seeking to raise $50,000 of the needed $2,000,000.

Here is how the $50,000 to be raised will be spent:

For nation-wide research and education	$25,000
For a Minnesota-Dakota Rheumatism Diognostic Center at the Mayo Clinic	10,000
For a special course in rheumatism for Minnesota and Dakota practicing physicians, to be conducted at the University of Minnesota	8,000
For studies, plans and public education concerning what ought to be done about the rheumatism problem in Minnesota and the Dakotas	7,000
Minnesota-Dakota goal	$50,000

One of the most effective uses which can be made of funds retained by the local Chapters is the support of beds which will be used for the study of arthritis and other rheumatic diseases. Only government funds can hope to cope with the enormous cost of beds for chronic custodial care. Private funds, however, spent primarily on beds which are used to study arthritis and other rheumatic diseases, may open the way to the discovery of better means for prevention and cure. And, while this search goes on, they will help immediately to prevent chronic crippling deformity.

C. W. Fogarty, Jr., M.D.

BETTER MEDICAL DENTAL INTEGRATION

WE HAVE before us a report by the joint committee from the Rhode Island Medical Society and the Rhode Island State Dental Society on medical-dental relations. The function of the committee was to study the existing relations and make recommendations for improving them. This report has recently been widely disseminated in the hope that improvements in the various phases of inter-relationship between the two professions, from the standpoint of education, practice, research, not only in Rhode Island, but on a national scale, will result.

The medical schools may justly be accused of neglecting the dental field in their training of physicians. Possibly the dental schools have restricted the teaching of dentistry to too narrow a field. We *do* know that the average physician knows little about the science of dentistry and as a rule, is content to leave treatment problems to the dentist. Why should the physician consider as his field the entire patient—except his teeth? It is certainly to the advantage of the

patient if his dentist knows when symptoms appearing in the mouth indicate medical consultation.

The Council on Education and Hospitals of the AMA has advocated the inclusion of dental departments in hospitals throughout the country. The Council on Education of the American Dental Association has supported the measure by setting up standards for hospital dental internships and residencies. This is a practical and desirable step for the larger hospitals and would facilitate the establishment of medical-dental clinics for reciprocal exchange of professional knowledge.

In the field of research there is need for cooperation between the medical and dental professions. The problem of the prevention of dental caries must be one of disturbed metabolism which neither profession, so far, has solved. Hospital medical-dental clinics might afford material for research in this field. The value of fluorine in the prevention of dental caries can be determined only by widespread trial.

We believe the Rhode Island Medical and Dental Societies have made a valuable contribution in calling attention to the desirability of more dental instruction of medical students and more medical instruction of dental students; the establishment of medical-dental clinics in hospitals, and more exchange of knowledge by the two professions through the medium of societies and publications.

"LABORATORY ABUSE"

IN THE editorial column of MINNESOTA MEDICINE (July, 1947) under the caption "Laboratory Abuse," was published a discussion against excessive laboratory procedure. It may be of interest to call attention to what our British Colleagues have said recently on the same subject.

Under the title "Where are We Going?" in the *British Medical Journal* of March 13, 1948, Franggon Roberts, Honorary Physician in charge of Douty X-Ray Clinic, Addenbrooks Hospital, Cambridge, discusses in the most striking and philosophical manner the mounting costs for x-ray examinations which is due to a terrific increase in requests. Since 1945, cost of hospital care, cost of out-patient attendants, and the number of pathological examinations have risen enormously. The ground he covers in trying to arrive at the logic of all this is a commentary on what is going on in the practice of medicine today. Every physician interested in the trends in practice should read this paper.

In Edinburgh, Edward B. Hendry, B.Sc., Ph.D., M.D., Ch.B., in a paper entitled "Medicine as a Planned Economy" (The Biochemist's View) in the *British Medical Journal*, (Sept. 1948) was inspired no doubt by Roberts' paper. He discusses the experiences in the biochemical laboratory of the Royal Infirmary. The rise of requests for laboratory examinations has risen very rapidly since 1945. He quotes Roberts' apt remark on this rise which he calls an "acceleration toward infinity." Dr. Hendry's discussion of the portent of this acceleration is interesting reading. To quote his conclusions:

> "Everyone must agree that the alarming increase in the number of laboratory examinations must stop or be stopped before things reach the stage of becoming a farce. It would give rise to a good deal of acrimonious debate whether the process should be stopped by the clinician, by the laboratory staff, or by the hospital authorities, and whether it should be stopped by innuendo, persuasion, coercion, or compulsion. I do not propose to allow myself to become entangled in this delicate point.
>
> It is a great pity that there is not more collaboration between clinical and laboratory staffs. Active co-operation could do much to root out obsolete and unnecessary work and in other cases investigations, which are of importance, could be substituted with advantage to all."

With the present agitation in this country regarding socialized medicine, the extreme interest of the lay press in the discussion, the intense scrutiny which the lay press and the medical press are giving the English experiment, makes these two papers exceedingly interesting communications—to which every honest physician should run to read.

A large share of the success in controlling the disease (tuberculosis over the years should probably be credited to the intensive educational campaign through which the average person has been taught the importance of early diagnosis and treatment, the recognition of the characteristic symptoms, and the measures to be taken to prevent the spread of the disease. The large number of tuberculosis clinics and sanatoria have also played an important role in saving the lives of tuberculous patients. —LOUIS I. DUBLIN, PH.D., *Health Progress* 1936 to 1945, Metropolitan Life Insurance Co.

MEDICAL ECONOMICS

NEWSPAPERS ALERT TO MEDICAL MUDDLERS

Minnesota journalists are keenly aware of the dangers inherent in the various plans for putting medical practice under government control. Excerpts from selected editorials show the trend of thought in the Upper Midwest, a trend that is encouraging to physicians, who sometimes feel that they are alone in the fight against socialism.

The *St. James Plaindealer* cites some of the fallacies in the compulsory health scheme by saying:

"To give such service free would obviously take a much larger physical plant than this nation possesses, and we possess the best that the world has produced. One thing that would surely happen in a program such as is suggested: Try as we would and be as conscientious that man can be, there would be a steady deterioration in the quality of the services rendered, the appearance of assembly line techniques and a gradual disappearance of traditional doctor-patient relationships."

Job Seekers Want It

"Congressional investigation has proved that chief propagandists for socialized medicine are those who conceive of themselves as holding important positions in a future medical bureaucracy," asserts the *Rushmore Enterprise*. "Their testimony is manifestly not that of neutral observers. The crocodile tears they shed with respect to the medical treatment received by the common citizen serves to disguise from the latter that under private medicine he is the best cared for patient in the world. Essentially, the politician is insisting upon the right to act as broker between doctor and patient on the theory, apparently, that the latter is incompetent to safeguard his own interests."

How private medicine and government medicine differ is illustrated in this striking manner by the *Vesta Vision:*

"No doubt you heard the warning over the radio, or read it in the daily paper, against the use of certain drugs as a substitute for salt. There have been three or four deaths from the use of the salt substitute, and the American Medical Association issued the warning. BUT the drug had been APPROVED by the Pure Food and Drug Administration. The Pure Food and Drug Administration is the Government agency; the American Medical Association represents individualism in medicine, the opposite of State Medicine."

Doctors Not Arbitrary

The *West Concord Enterprise* sets the record straight on the position of doctors in the socialized medicine vs. private medicine conflict:

"If anyone has an idea that the physicians of this country are fighting any and all plans that would give the American people better medical attention at a cost which is within their means, he is sadly misinformed. It is true that the great majority of doctors are strongly opposed to compulsory government health insurance, and kindred schemes which would open the gates wide to completely socialized medicine. The basic reason for this opposition is found in a statement issued by the American Medical Association, which said: 'The experience of all countries where government has seized control of medical care has been progressive deterioration of the standards of that care to the serious detriment of the sick and needy.'"

Taking the long view, the *Austin Daily Herald* cites the approach of complete socialism.

"The compulsory health insurance plan is simply one of the planks in a platform that would create a total state. Lenin himself ranked socialization of medicine high among Communist objectives. And socialized medicine will come as surely as night follows day if we give the bureaucrats control over medical practice."

Warns of Wrong Route

The *Little Falls Daily Transcript* warns against the loss of present high quality medical care.

"With the exception of compulsory insurance plans, the developments in the field of medicine are taking place through the efforts of medical personnel and a forward-looking public. As plans for socialization of American medicine are advanced, we must look to the high calibre of present medical service and ask ourselves if we want to take chances with governmental control of this service in the future. Adequate medical atten-

tion for all is a goal toward which we must aim. But let us not take the wrong route."

American people are not helpless against the burden of sickness costs, declares the *Hibbing Daily Tribune*, despite:

"One of the basic implications in arguments on behalf of compulsory health insurance is that the bulk of the American people are almost totally incapable of dealing with illness when it strikes."

"That implication is not supported by the facts," asserts the *Tribune*, quoting enrollment figures from the voluntary prepayment plans. ". . . their (voluntary plans) growth is both steady and rapid, the cost is low, the extent of coverage has been substantially broadened, and they clearly provide the soundest approach yet devised to the problem of paying for medical attention."

Two Kinds of Patients

"Some authorities believe that the weakest link in the chain of medical care and national health is composed of two kinds of individuals," states the *Mankato Free Press*. "One kind is the fellow who is sure he is as healthy as a horse and has the constitution of one, and so he never sees a doctor from one year to the next. The other is the fellow who knows something is wrong, but does not go to a doctor because he scorns doctors or is afraid of them or afraid of what they might tell him. No program yet proposed seems to offer much hope of solving that problem."

The shooting-butterflies-with-a-shotgun method is scorned by the *Harmony News* which believes:

"There is a small percentage of the population which is actually indigent, and which cannot deal with the problems of illness without outside aid. But certainly, this group can be cared for without taxing the American people billions a year for a compulsory scheme for all—and without setting the stage for completely socialized medicine. It has been factually supported time and time again by the records made in various countries where regimented or socialized medicine has been tried, that *science does not flower in a political climate.*"

The *Fergus Falls Daily Journal* quotes doctors claim that:

". . . the system will result in complete demoralization in medicine in the course of time."

REGIONAL MEETING TO AID LOCAL HEALTH UNIT PLAN

Promoting the plan for full time health departments throughout the nation are regional meetings. Two have already taken place and one is scheduled for April 25, 26 and 27, in Omaha.

Five midwestern states met in Mitchell, Indiana, and five Rocky Mountain states at Salt Lake City. The Omaha session will include teams of ten from Minnesota, Iowa, Nebraska and North and South Dakota.

Sponsor of the meetings—the National Advisory Committee on Local Health Units—suggests that best results are obtained when the teams include representatives from the official health agency; the medical, nursing, dental and pharmaceutical professions; the civic organizations, such as the Parent-Teachers Association, the Federation of Women's Clubs, the Business and Professional Women's Clubs, the Lions, Kiwanis, Rotary; farm organizations such as the Grange, Farm Bureau, Farmers Union Cooperative; labor and industry—AF of L, CIO, Chamber of Commerce; the voluntary health agencies—tuberculosis and health associations, Cancer Society, American Red Cross, Infantile Paralysis Foundation and any other representative organizations.

The idea is to develop a nucleus within the state for promoting a public health program.

WHAT'S HAPPENING IN HEALTH EDUCATION?

St. Louis County has divided its health education program into five categories, beginning with an educational program for the Medical Society and Auxiliary. The speakers' bureau, organized under the direction of Dr. W. A. Coventry, has arranged for medical talks at all service clubs and almost all civic groups. Liaison with various organizations, many of them medically allied, is the third division of the program and, by this means, assistance has been given in obtaining and preparing direct-mail material. The doctors are also assisting lay persons in framing letters to their congressmen, protesting against the compulsory health insurance proposal. Newspaper and radio co-operation is being sought, with marked success, by the fifth division of the society. Local news commentators are using medical news and the newspapers have responded with what St. Louis county spokesmen describe as "excellent publicity."

Ramsey County Auxiliary is filling its niche in the state-wide Community Health Day schedule, April 21. The Ramsey County session, emphasizing women's health, health and behavior

problems of children, the community's role in improving health conditions, will be held in the theatre section of the Saint Paul Auditorium.

Stearns-Benton Medical Society has conducted a three-week series of medical broadcasts over Radio Station KFAM, St. Cloud. The Monday-Wednesday-Friday programs centered around such subjects as hospital costs and facilities and the doctors' connection with hospitals, the DP physician, local care for indigents, Blue Cross and Blue Shield and the Ewing, Brookings and Friedman reports. The concluding show was entitled "Would You Like To Become a Doctor?" Newspaper advertisements and radio spot announcements promoted the series which Medical Society members felt was highly successful.

TABLOID TO BRING HEALTH NEWS TO MINNESOTANS

Minnesota health standards rank high in a nation that holds the best health records in the world. Facts about Minnesota's health, the state's growing importance as a world medical center, advances made in the conquest of heart disease, cancer, and other diseases which rob the state of far too many citizens, information about the voluntary pre-payment systems for financing medical and hospital care are included. By statement and implication the fact is made clear that only where medical practice and research is free of governmental control could this progress against disease have been made.

The tabloid, an eight-page publication, will be distributed to 200,000 selected rural and industrial families in the state. Subsequent issues are planned for the year. Physicians will receive their copies with their regular monthly *Newsletter.*

Saint Paul, Minnesota

Julian F. DuBois, M.D., Secretary

Minneapolis Abortionist Ordered to Serve Four-year Prison Term

Re. State of Minnesota vs. Martin Peter Schmit, et al.

On March 17, 1949, Martin Peter Schmit, forty-nine years of age, 127 East 14th Street, Minneapolis, was sentenced by the Hon. William A. Anderson, Judge of the District Court of Hennepin County, to a term, not to exceed four years, at hard labor in the State Prison at Stillwater. The defendant had entered a plea of guilty on February 14, 1949, in Judge Anderson's Court, to information charging the defendant with the crime of abortion. Judge Anderson refused to place the defendant on probation and ordered him to serve the sentence.

Schmit was arrested on February 9, 1949, following an investigation made by the Minnesota State Board of Medical Examiners and the Minneapolis Police Department, into the circumstances surrounding a criminal abortion performed by the defendant on or about January 25, 1949, on a twenty-year-old, unmarried, Minneapolis girl. The patient became seriously ill and was hospitalized in a Minneapolis hospital. The patient stated that the abortion was performed by the defendant by means of a catheter and that the defendant was paid $200 for his services. Subsequent investigation disclosed that the defendant had performed numerous other abortions during the past year. The defendant at the time of being sentenced admitted that he had performed twenty-five abortions. He further stated that he charged from $50.00 to $200.00 for each abortion.

Schmit stated that he was born January 5, 1900, at Chamberlain, South Dakota; that he received his grade school education in Yellow Medicine County, Minnesota; that he subsequently worked as a mechanic, welder and salesman in Minnesota. Schmit admitted that he had no training in medicine or surgery and that he had no license to practice any form of healing in the state of Minnesota or anywhere else.

* * *

Minneapolis Tailor Sentenced on Abortion Charge

Re. State of Minnesota vs. Raymond P. Alberts.

On April 5, 1949, Raymond P. Alberts, forty-four years of age, residing at the Minnesotan Hotel, Minneapolis, was sentenced by the Hon. John A. Weeks, Judge of the District Court of Hennepin County, following the defendant's entering a plea of guilty on March 11, 1949, to an information charging him with the crime of abortion. The sentence imposed by the Court was "according to law." Judge Weeks suspended the sentence and placed the defendant on probation for five years. The defendant was arrested on March 5, 1949, following an investigation into an abortion performed on a twenty-four-year-old unmarried Minneapolis woman. The investigation disclosed that the abortion had been performed by the defendant by means of a catheter. There was no evidence that any consideration was paid for the abortion.

The defendant, at the time of his arrest, was employed as a tailor in a Minneapolis department store. Upon being questioned by the Court, Alberts stated that he was born at Fond du Lac, Wisconsin. The defendant admitted that he had three prior convictions for felonies, the first one in 1919, in the Circuit Court at Fond du Lac, Wisconsin, on a charge of rape. For that offense the defendant was sentenced to a ten-year term in the Wisconsin State Prison. After serving two and one-half years, the defendant was transferred to the Wisconsin State Reformatory at Green Bay. Upon being released, the defendant was convicted in November, 1926, in the Circuit Court of Milwaukee of the offense of grand larceny, and also of armed robbery. The defendant received a combined sentence of three to fifteen years for those two offenses. The defendant served until May 7, 1932, at which time he was released on parole. The Court stated to the defendant that he was giving him another opportunity to make good in view of the fact that there was no evidence that the defendant had violated any laws since his conviction in Milwaukee in 1926 up to the present case. Alberts admitted that he never studied medicine nor any of the other healing arts.

MINNESOTA STATE MEDICAL ASSOCIATION

Ninety-Sixth Annual Meeting

Saint Paul Auditorium, Saint Paul, Minnesota
May 9, 10 and 11, 1949

ANNOUNCEMENTS

Presiding officers at each session have been instructed by the Committee on Scientific Assembly to show a blue light on the speakers' rostrum two minutes before the end of each speakers' program time. A red light will show when his time is up.

REGISTER AND SECURE YOUR BADGE at the Registration Desk at the Saint Paul Auditorium at 8:00 A.M. Admittance will be by badge only. Arrangements have been made with the hospitals to admit interns and key hospital personnel as guests *if previously certified.* Out-of-state physicians can secure guest badges by presenting their membership cards from their local county and state medical societies.

TELEPHONE SERVICE: All physicians attending the Annual Meeting are reminded to tell their home and office secretary how they can be reached during their attendance in Saint Paul. Special incoming lines have been installed at the Auditorium Registration desk. All local and long distance calls will be handled promptly by directing calls to the Minnesota State Medical Association at the Saint Paul Auditorium—*Cedar 1374.*

BRING YOUR MEMBERSHIP CARD: There will be no registration fee for those who present a membership card or receipt or other evidence from their county society or the state association or the American Medical Association, nor for members of associated professions including dentists, pharmacists, interns, nurses, hospital personnel, teachers or social welfare workers who present invitations or other identification.

BADGES: You are requested to wear your badge while you are on the convention floor. This is important and will greatly assist us to eliminate undesirable persons such as cranks and pickpockets who so frequently try to take advantage of meetings of this character.

PARKING: Good parking space is available next to the Auditorium.

VISIT THE EXHIBITS: In keeping with established custom, forty-five minute recess periods have been provided each day, during which time those attending the Annual Meeting are urged to visit the scientific and technical exhibits. There is something of interest and education in the large exhibit of technical displays. Stop and show your appreciation of the exhibitors' support in helping to make successful the 1949 MSMA Convention.

SCIENTIFIC CINEMA: A full day's program of interesting medical motion pictures has been provided by the *Medical Film Guild* and will be shown in the *West Arena.* Detailed information on the films and the projection schedule will be found on page 10.

ROUND TABLE LUNCHEONS: A series of twenty-one Round Table Discussion Luncheons have been arranged for this meeting. One luncheon is scheduled for Monday; ten will be held on Tuesday, and ten on Wednesday. Tickets may be purchased in advance for these luncheons, all of which are held at 12:15 p.m. at either the Hotel Saint Paul or Hotel Lowry. Lists of subjects and leaders are printed in the program on pages 17 and 19 and on the reservation cards mailed with the program. Attendance at each luncheon is limited; latecomers are accommodated according to their choice if limits have not already been reached. Tickets $2.00, tips included.

MEDAL: The Southern Minnesota Medical Association will again award a medal to the individual physician presenting the outstanding scientific exhibit. The award will be made at the banquet Tuesday evening, May 10, at Hotel Saint Paul.

FIFTY CLUB: Tribute will be paid to those members who this year have completed fifty years of practice in Minnesota by election to Minnesota's "Fifty Club." Candidates will be honor guests at the Ninety-sixth Annual Banquet, 7:00 p.m. Tuesday, May 10, Hotel Saint Paul, and will be presented with lapel buttons and certificates at that time.

WOMAN'S AUXILIARY: Physicians' wives attending the meeting may secure programs for the business and social sessions of the Woman's Auxiliary at the Women's Registration Desk in the lobby of Hotel Saint Paul. All visiting women are cordially invited to attend the special events arranged by the hostesses of the Ramsey County Medical Auxiliary. Among these is a tea Monday afternoon at the Women's City Club of Saint Paul, and the Annual Meeting and Luncheon at 10:00 a.m. and 1:00 p.m., respectively, at the Minnesota Club.

SPECIAL SESSIONS

In addition to the general sessions to be held on Monday, Tuesday and Wednesday in the Auditorium Theater on the ground floor to the right of the exhibition hall, there will be *five* special section meetings in Stem Hall (to the right of the exhibition hall). These will be held during the morning of each of the three con-

vention days and Monday and Tuesday afternoons. Intermission periods will be observed from 10:15 a.m. to 11:00 a.m. and again from 3:15 p.m. to 4:00 p.m. at each session so that those who attend may visit exhibits, demonstrations and the scientific cinema.

Monday, May 9

A Symposium on Orthopedic and Fracture Surgery has been arranged for *9:00 a.m.* Monday in *Stem Hall.* The program is open to all convention visitors.

The Minnesota Chapter of the American College of Chest Physicians will hold a special session on chest diseases Monday afternoon beginning at *2:00* in *Stem Hall.*

Tuesday, May 10

A Special Symposium on Research Problems will be held on Tuesday morning at *9:00* in *Stem Hall.*

Two illustrated lectures will feature the special session in Stem Hall starting at 2:00 Tuesday afternoon.

Wednesday, May 11

The Minnesota Academy of Ophthalmology and Otolaryngology is sponsoring a special program at *9:00* in *Stem Hall.*

DEMONSTRATIONS

Obstetric Manikin Demonstrations: A discussion of delivery problems and technics, with the use of the manikin, provided through the courtesy of the Minnesota Department of Health will be incorporated as a part of special luncheons held on each of the three days of the Annual Meeting; and at 5:15 p.m. in *Stem Hall* at the Auditorium on Monday and Tuesday.

Demonstration on Oxygenation During Anesthesia will be presented by the Section on Anesthesiology, Mayo Clinic, before each morning and afternoon general and special session and during intermission periods in the Scientific Exhibit Section S-8.

Demonstration on the Therapy of Irradiated Plasma and Plasma Substitutes will be sponsored by the Committee on First Aid and Red Cross during intermission periods and before each morning and afternoon scientific session in S-9 in the Scientific Exhibit Section.

Demonstration on the Physics of Atomic Energy will be presented by the Council on Physical Medicine of the American Medical Association, before each morning and afternoon scientific session in S-13 in the Scientific Exhibit section, and during intermissions. By means of demonstrative apparatus and charts, the Geiger-Muller Counter will be explained. Demonstrations will show the use of instruments in medicine and allied sciences.

GUEST SPEAKERS

We are indebted to the following societies and organizations for guest speakers at this meeting:

The Minnesota Academy of Ophthalmology and Otolaryngology—Speaker, RALPH O. RYCHENER, Associate Professor of Ophthalmology, College of Medicine University of Tennessee, Memphis.

The Minnesota Department of Health—Obstetric Manikin Demonstrators, HOWARD J. HOLLOWAY, Associate in Department of Obstetrics & Gynecology, Northwestern University Medical School, Evanston; and JOHN H. RANDALL, Professor of Obstetrics and Gynecology, College of Medicine State University of Iowa, Iowa City.

The Minnesota Radiological Society—Speaker, H. DABNEY KERR, Professor and Head of the Department of Radiology, College of Medicine State University of Iowa, Iowa City, who will deliver the annual *Russell D. Carman Memorial Lecture in Radiology.*

The Minnesota Society of Clinical Pathologists—Speaker, LEONARD W. LARSON, Bismarck, who will deliver the annual *Arthur H. Sanford Lectureship in Pathology.*

The National Foundation for Infantile Paralysis, Inc.—Speaker, ROBERT B. LAWSON, Department of Pediatrics, The Bowman Gray School of Medicine, Wake Forest College, Winston Salem, North Carolina.

The Northern Minnesota Medical Association—Speaker, CARL P. HUBER, Professor of Obstetrics and Gynecology, Indiana University School of Medicine, Indianapolis.

Other visiting speakers at this meeting:

RALPH E. CAMPBELL, Professor of Obstetrics and Gynecology, University of Wisconsin Medical School, Madison.

RONALD R. GREENE, Assistant Professor of Obstetrics and Gynecology, Northwestern University Medical School, Chicago.

LOUIS J. LIMARZI, Hematologist, University of Illinois College of Medicine, Chicago.

GUSTAF E. LINDSKOG, Professor of Surgery, Yale University School of Medicine, New Haven, Connecticut.

WALTER L. PALMER, Professor of Medicine, University of Chicago School of Medicine, Chicago.

ROY GLEN SPURLING, Senior Consultant in Neurosurgery to the Veterans Administration, Louisville, Kentucky.

SOCIAL EVENTS

Annual Banquet: The annual dinner for members, their wives and guests will be held at 7:00 p.m. Tuesday, May 10, in the *Continental Room* of *Hotel Saint Paul.* Ernest M. Hammes, St. Paul President of the Minnesota State Medical Association, and Colonel Jack Major, Paducah, Kentucky, will be banquet speakers. Tickets $4.00.

President's Reception: Dr. and Mrs. Ernest M. Hammes cordially invite all members of the Minnesota State Medical Association, their wives and convention guests to a Reception at the Minnesota Club from five to six-thirty o'clock immediately preceding the Banquet. Cocktails.

"Variety Night": All convention visitors and their wives will be guests of the Ramsey County Medical Society and the Minnesota State Medical Association for an evening of light comedy, music and dancing, Monday evening at 8:30 p.m. in the *Continental Room* of *Hotel Saint Paul.*

Medical Veterans of World War II will meet at a luncheon at 12:30 p.m. on Monday, May 9, in the Continental Room at Hotel Saint Paul. This is a good opportunity to meet the fellows again; let's make it One Hundred Per Cent (To quote Dr. A. N. Bessessen, Jr., President). Tickets may be secured at the registration desks. Make reservations in advance with Dr. A. N. Bessessen, Jr., 550 Medical Arts Bldg., Minneapolis 2.

Medical Women's Luncheon: Dr. Della Drips, Rochester, President, announces a luncheon meeting of the Medical Women's Association on Monday, May 9. Open to all visiting women doctors. Dr. Selma Mueller of Duluth is expected to talk on her medical service in the Orient. Make reservations in advance with Dr. Nellie N. Barsness, 540 Lowry Medical Arts Bldg., St. Paul 2.

Minneapolis General Hospital Surgical Residents Society will hold their annual dinner for members and wives at 7:00 p.m. on Sunday, May 8, at the University Club, 420 Summit Avenue, St. Paul. For reservations contact Ed Benjamin, 1727 Medical Arts Bldg., Minneapolis 2.

Minnesota Chapter, American College of Chest Physicians Luncheon: At noon, Monday, May 9, the Minnesota Chapter of the American College of Chest Physicians will hold a luncheon meeting in Room 334 of Hotel St. Paul at 12:15 p.m. Reservations should be made in advance with Dr. S. S. Cohen, Oak Terrace.

Minnesota Radiological Society will hold their annual dinner for members and wives at 6:00 p.m. on Monday, May 9, at the St. Paul Athletic Club, 340 Cedar Avenue. Guest speaker will be Dr. H. Debney Kerr of Iowa City, who will discuss "The Place of Radiation

Therapy in Intracranial Neoplasms." Reservations should be made in advance with Dr. Paul Medelman, 572 Lowry Medical Arts Bldg., St. Paul 2.

Minnesota Society of Clinical Pathologists will hold their annual dinner meeting for members and their wives on Wednesday evening, May 11. For reservations contact Dr. Kano Ikeda, Miller Hospital, 125 College Ave., W., St. Paul 2.

Nu Sigma Nu Reunion: The annual get-together of members of the Nu Sigma Nu Medical Fraternity will be held at the Minnesota Club, 317 Washington Street, St. Paul, on Monday, May 9. Cocktails from 5:00 to 7:00 p.m. For dinner reservations, kindly make reservations well in advance with Dr. Charles N. Hensel, 613 Lowry Medical Arts Bldg., St. Paul 2.

Phi Beta Pi Medical Fraternity Luncheon: All members of Phi Beta Pi Medical Fraternity are invited to attend a luncheon meeting at 12:15 p.m., Tuesday, May 10. Plans will be announced later and tickets will be on sale at the Registration Desk at the Auditorium. Arrangements in charge of Dr. B. G. Lannin, 1464 Lowry Medical Arts Bldg., St. Paul 2, and Dr. F. F. Wipperman, 1921 Medical Arts Bldg., Minneapolis 2.

SPORT EVENTS

Golf Tournament: The Annual Golf Tournament of the Minnesota State Medical Association will be held Sunday, May 8, at the *Town and Country Club, 2279 Marshall Avenue, St. Paul,* with tee-off at 11:00 a.m. All medical golfers are invited to enter and compete for the attractive prizes that have been donated. Victor P. Hauser, St. Paul, is tournament chairman.

Sport Event I: "Fifty-Bird Event Skeet Shoot" for Malcolm Pfunder Trophy, donated by Dr. Malcolm Pfunder of Minneapolis will be held from 10:00 a.m. to 4:00 p.m. on Sunday, May 8, at Minnesota State Fair Skeet Club—State Fair Grounds, St. Paul.

Sport Event II: Duck Hunters' Special "Razzle-Dazzle 25-Bird Event" for Leech Lake Trophy, donated by Dr. Vernon D. E. Smith.

Scientific Program

Monday, May 9

SECTION I—GENERAL SESSION

A.M.

8:30 Demonstrations—S-8, S-9 and S-13
Visit Scientific and Technical Exhibits ..... Arena

9:00 Scientific Cinema—Medical Film Guild ..... West Arena

9:00 *Clinico-Pathological Conference* ..... Auditorium Theater
Subject: INTESTINAL OBSTRUCTION—J. Arnold Bargen, Rochester, Moderator
Roentgenological Aspects—Leo G. Rigler, Minneapolis
Differential Diagnosis—Walter L. Palmer, Professor of Medicine, University of Chicago, School of Medicine, Chicago, Illinois

10:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

11:00 MANAGEMENT OF INTESTINAL OBSTRUCTION ..... Auditorium Theater
Medical Aspects—Walter L. Palmer, Professor of Medicine, University of Chicago, School of Medicine, Chicago, Illinois
Surgical Aspects—Malcolm G. Gillespie, Duluth

P.M.

Afternoon

12:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Fiesta Room, Hotel Lowry
John H. Randall, Professor of Obstetrics and Gynecology, State University of Iowa College of Medicine, Iowa City, Iowa

1:30 Visit Scientific and Technical Exhibits ..... Arena

1:30 Demonstrations—S-8, S-9 and S-13

2:00 Scientific Cinema—Medical Film Guild ..... West Arena

2:00 TRAUMA TO THE NERVOUS SYSTEM ..... Auditorium Theater
Ernest M. Hammes, Jr., Saint Paul, Moderator
Head Injuries—Leonard A. Titrud, Minneapolis
Spinal Cord Injuries—George S. Baker, Rochester
Peripheral Injuries—Roy Glen Spurling, Senior Consultant in Neurosurgery to the Veterans Administration, Louisville, Kentucky

3:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

4:00 RUSSELL D. CARMAN MEMORIAL LECTURE ..... Auditorium Theater
Roentgen Diagnosis of Lesions of the Urinary Tract—H. Dabney Kerr, Professor and Head of the Department of Radiology, State University of Iowa, College of Medicine, Iowa City, Iowa
Presentation of Speaker: John D. Camp, Rochester, President, Minnesota Radiological Society

5:00 Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena

5:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Stem Hall
John H. Randall, Professor of Obstetrics and Gynecology, State University of Iowa, College of Medicine, Iowa City, Iowa

8:30 "VARIETY NIGHT" ..... Continental Room, Hotel Saint Paul

Monday, May 9

SECTION II—SPECIAL SESSION

A.M.

9:00 ORTHOPEDIC AND FRACTURE SURGERY ..... Stem Hall
Wallace Cole, Saint Paul, Chairman
Slipping of the Upper Femoral Epiphysis—Stewart W. Shimonek, Saint Paul

9:15 *Carpal Injuries*—Malvin J. Nydahl, Minneapolis

9:30 *Delayed Primary Closure of Wounds*—Frank S. Babb, Saint Paul

9:45 *Orthopedic Aspects of Poliomyelitis*—John F. Pohl, Minneapolis

10:00 *Fractures of the Femoral Shaft*—Harry B. Hall, Minneapolis

10:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

11:00 ORTHOPEDIC AND FRACTURE SURGERY (Continued) ..... Stem Hall
Fractures of the Spine—John C. Ivins, Rochester
11:15 *Carpo-navicular Injuries*—Carl G. Caspers, Minneapolis
11:30 *Fractures of the Forearm*—Richard E. Reiley, Minneapolis
11:45 *Congenital Dislocations of the Hip*—Vernon L. Hart, Minneapolis (Motion picture)

P.M. *Afternoon*
12:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Fiesta Room, Hotel Lowry
John H. Randall, Professor of Obstetrics and Gynecology,
State University of Iowa, College of Medicine, Iowa City, Iowa
1:30 Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13
2:00 Scientific Cinema ..... West Arena
2:00 MINNESOTA CHAPTER OF THE AMERICAN COLLEGE OF CHEST PHYSICIANS .... Stem Hall
Karl H. Pfuetze, Cannon Falls, Chairman
Cytologic Examination of Sputum as an Aid in the Diagnosis of Bronchogenic Carcinoma—John R. McDonald, Rochester
Discussion: Kano Ikeda, Saint Paul—DeForest R. Hastings, Minneapolis
2:30 *Diagnosis and Treatment of Common Forms of Respiratory Allergy*—Fred W. Wittich, Minneapolis
Discussion: Leo G. Rigler, Minneapolis—George C. Roth, Saint Paul

3:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13
4.00 CHEST PHYSICIANS (Continued) ..... Stem Hall
Reversible Forms of Heart Disease—John F. Briggs, Saint Paul
Discussion: Richard L. Varco, Minneapolis—Joseph F. Borg, Saint Paul
4:30 *Differential Diagnosis of Pulmonary X-Ray Shadows*—Hilbert Mark, Minneapolis
Discussion: Gust A. Hedberg, Nopeming—Sumner S. Cohen, Oak Terrace
5:00 Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
5:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Stem Hall
John H. Randall, Professor of Obstetrics and Gynecology,
State University of Iowa, College of Medicine, Iowa City, Iowa

8:30 "VARIETY NIGHT" ..... Continental Room, Hotel Saint Paul

All convention visitors and their wives will be guests of the Ramsey County Medical Society and the Minnesota State Medical Association for an evening of light comedy, music and dancing, Monday, at 8:30 p.m. featuring
The Atomic Bums—Noted Barbershop Quartet
Episodes in the Life of a Doctor's Wife—Hennepin County Medical Auxiliary
Dancing to the Music of the *Imperials*
Light refreshments will be available during the dancing in the Continental Room.

Everybody is invited to attend.

Tuesday, May 10

SECTION I—GENERAL SESSION

A.M.
8:30 Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13
9:00 Scientific Cinema—Medical Film Guild ..... West Arena
9:00 CLINICO-PATHOLOGICAL CONFERENCE ..... Auditorium Theater
Subject: DISEASES OF THE THORAX
John F. Briggs, Saint Paul, Moderator
Roentgenological Aspects—Walter H. Ude, Minneapolis
Differential Diagnosis—Gustaf E. Lindskog, Professor of Surgery, Yale University School of Medicine, New Haven, Connecticut

10:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13
11:00 MANAGEMENT OF DISEASES OF THE THORAX ..... Auditorium Theater
Anesthesiological Aspects—Joe William Baird, Minneapolis
Surgical Aspects—Gustaf E. Lindskog, Professor of Surgery, Yale University School of Medicine, New Haven, Connecticut

P.M.

Afternoon

12:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Fiesta Room, Hotel Lowry
Howard J. Holloway, Associate in the Department of Obstetrics and Gynecology, Northwestern University Medical School, Evanston, Illinois

12:15 ROUND TABLE LUNCHEONS

1:30 Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

2:00 Scientific Cinema—Medical Film Guild ..... West Arena

2:00 A REVIEW OF CURRENT MANAGEMENT OF THE BLOOD DYSCRASIAS .. Auditorium Theater
Frank J. Heck, Rochester, Moderator
John J. Boehrer, Jr., Minneapolis
Dorothy Sundberg, Minneapolis
Louis J. Limarzi, Hematologist, University of Illinois, College of Medicine, Chicago, Illinois

3:15 *Intermission*

Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

4:00 THERAPEUTIC PROBLEMS ENCOUNTERED IN ACUTE POLIOMYELITIS .. Auditorium Theater
Robert B. Lawson, Department of Pediatrics, The Bowman Gray School of Medicine, Wake Forest College, Winston Salem, North Carolina
Presentation of Speaker: Elizabeth C. Lowry, Minneapolis, Secretary Northwestern Pediatrics Society

5:00 Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena

5:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Stem Hall
Howard J. Holloway, Associate in the Department of Obstetrics and Gynecology, Northwestern University Medical School, Evanston, Illinois

5:00 PRESIDENT'S RECEPTION ..... The Minnesota Club
Dr. and Mrs. Ernest M. Hammes cordially invite all members of the Minnesota State Medical Association, their wives and convention guests to a Reception at the Minnesota Club from five to sixty-thirty o'clock. Cocktails.

7:00 ANNUAL BANQUET ..... Continental Room, Hotel Saint Paul

Tuesday, May 10

SECTION II—SPECIAL SESSION

A.M.

9:00 SYMPOSIUM ON RESEARCH PROBLEMS ..... Stem Hall
James T. Priestley, Rochester, Chairman
Needle Biopsy of the Liver—Maurice H. Stauffer, Rochester

9:15 *The Occurrence of a Gastric Secretory Inhibitor in Gastric Mucin*—Henry V. Ratke, Rochester

9:30 *Cytologic Examination of Smears in the Diagnosis of Cancer of the Esophagus and Cardia of the Stomach*—Howard A. Anderson, Rochester

9:45 *Experimental Studies on Gastric Carcinogenesis*—Claude R. Hitchcock, Minneapolis

10:00 *Studies on External Pancreatic Secretion in Dogs with Chronic Pancreatic Fistula, with Emphasis on the Effects of Vagotomy*—Eric F. Routley, Rochester

10:15 *Intermission*

11:00 RESEARCH PROBLEMS (Continued) ..... Stem Hall
Cyanosis—Its Production and Effects—Timothy Takaro, Rochester

11:15 *Experimental Considerations in Restoration of Continuity of Superior Mesenteric Vessels*—Loren E. Nelson, Minneapolis

11:30 *The Dietary Treatment of Hypertension*—Carleton B. Chapman, Minneapolis

11:45 *The Treatment of Leukemia and Polycythemia*—Howard L. Horns, Minneapolis

P.M.

Afternoon

12:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Fiesta Room, Hotel Lowry
Howard J. Holloway, Associate in the Department of Obstetrics and Gynecology, Northwestern University Medical School, Evanston, Illinois

12:15 ROUND TABLE LUNCHEONS ..... Meeting Halls to be assigned. Hotel Lowry and Hotel Saint Paul
Laboratory Procedures in General Practice—Ellery M. James, Minneapolis
Fractures of the Elbow—S. Sverre Houkom, Duluth
Skin Diseases—Elmer T. Ceder, Minneapolis
Questions and Answers Concerning (1) Diagnosis and Treatment Hydronephrosis (2) Management of Vesical Neck Obstruction—Frederic E. B. Foley
Cancer of the Digestive Tract—Royal V. Sherman, Red Wing
Rheumatic Heart Disease—Charles N. McCloud, Jr., Saint Paul
Diabetes—Johannes K. Moen, Minneapolis
Hyperthyroidism—Samuel F. Haines, Rochester
Coronary Disease—Daniel W. Wheeler, Duluth

2:00 Use of Rectus Sheath and Superior Pubic Ligament in Direct Inguinal Hernia ..... Stem Hall, Auditorium
Illustrated Lecture: Hamlin Mattson, Minneapolis

2:20 Spinal Involvement in Poliomyelitis ..... Stem Hall, Auditorium
Illustrated Lecture: Frederic J. Kottke, Minneapolis

3:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

5:15 Obstetric Manikin Demonstration ..... Stem Hall
Howard J. Holloway, Associate in the Department of Obstetrics and Gynecology, Northwestern University Medical School, Evanston, Illinois

5:00 President's Reception ..... The Minnesota Club

7:00 Annual Banquet ..... Continental Room, Hotel Saint Paul
Presiding: John R. Aurelius, Saint Paul, President, Ramsey County Medical Society
Introduction of Mrs. Henry E. Bakkila, Duluth, President, Woman's Auxiliary
Presentation of Fifty Club Certificates
Presentation of Southern Minnesota Medical Association Medal
Presentation of Distinguished Service Medal
"The Minnesota Centennial—Its Medical History"—Ernest M. Hammes, Saint Paul, President, Minnesota State Medical Association
"Taxes Women and Hogs"—Colonel Jack Major, Paducah, Kentucky

Wednesday, May 11

SECTION I—GENERAL SESSION

A.M.
8:30 Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

9:00 Scientific Cinema—Medical Film Guild ..... West Arena

9:00 Clinico-Pathological Conference ..... Auditorium Theater
Subject: Endometriosis
Claude J. Ehrenberg, Minneapolis, Moderator
Theory of Causes and Hormonal Aspects—Ronald R. Greene, Assistant Professor of Obstetrics and Gynecology, Northwestern University Medical School, Chicago, Illinois
Pathological Aspects—Malcolm B. Dockerty, Mayo Clinic, Rochester

10:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

11:00 Management of Endometriosis ..... Auditorium Theater
Clinical Aspects—Carl P. Huber, Professor of Obstetrics and Gynecology, Indiana University School of Medicine, Indianapolis, Indiana
Surgical Aspects—Ralph E. Campbell, Professor of Obstetrics and Gynecology, University of Wisconsin Medical School, Madison, Wisconsin

P.M. *Afternoon*
12:15 Obstetric Manikin Demonstration ..... Fiesta Room, Hotel Lowry
John A. Haugen, Minneapolis

12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

2:00 Scientific Cinema—Medical Film Guild ..... West Arena

2:00 Manual Rotation of Occiput-Posterior Presentations ..... Auditorium Theater
Howard J. Holloway, Associate in the Department of Obstertics and Gynecology, Northwestern University Medical School, Evanston, Illinois

3:00 Arthur H. Sanford Lectureship in Pathology ..... Auditorium Theater
The Relation of the Pathologist to the General Practitioner—Leonard W. Larson, Bismarck, North Dakota, Former President of the American Society of Clinical Pathologists
Presentation of Speaker: Robert Hebbel, President, Minnesota Society of Clinical Pathologists

Wednesday, May 11

SECTION II—SPECIAL SESSION

A.M.
9:00 Minnesota Academy of Ophthalmology and Otolaryngology ..... Stem Hall
Avery De H. Prangen, Rochester, Chairman
Management and Treatment of Congenital and Adult Dacrocystitis—Ralph O. Rychener, Associate Professor of Ophthalmology, University of Tennessee College of Medicine, Memphis, Tennessee

10:15 *Intermission*
Scientific Cinema—Medical Film Guild ..... West Arena
Visit Scientific and Technical Exhibits ..... Arena
Demonstrations—S-8, S-9 and S-13

11:00 MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY (Continued) ..... Stem Hall
Osteoma of the Paranasal Sinuses—Olav E. Hallberg, Rochester—Joseph W. Begley, Jr., Rochester

P.M. *Afternoon*
12:15 OBSTETRIC MANIKIN DEMONSTRATION ..... Fiesta Room, Hotel Lowry
John A. Haugen, Minneapolis

12:15 ROUND TABLE LUNCHEONS—Meeting Halls to be assigned. ..... Hotel Lowry and Hotel Saint Paul
Skin Grafts—N. Logan Leven, Saint Paul
Hypertension—Frank J. Hirschboeck, Duluth
Peripheral Vascular Disease—John C. Hays, Saint Paul
Treatment of the Cervix—Wilford J. Deweese, Bemidji
Headaches—Walter P. Gardner, Saint Paul
Radioactive Isotopes—Charles F. Stroebel, Rochester
Emergency Ear, Nose and Throat Conditions—Kenneth A. Phelps, Minneapolis
Diverticulitis—John M. Waugh, Rochester
Office Procedures in Rectal Diseases—James K. Anderson, Minneapolis
Visit Scientific and Technical Exhibits ..... Arena

TREATMENT
OF CONSTIPATION
IN
mucous colitis

"The treatment of the constipation in mucous colic does not differ from the treatment of uncomplicated constipation. It is, as always, of great importance to avoid irritating aperients, ... The stools should be rendered soft and more bulky and therefore more easy to expel with . . . and unirritating vegetable mucilages."

—Hurst, A., in Portis, S. A.: Diseases of the Digestive System, ed. 2, Philadelphia, Lea & Febiger, 1944, p. 692.

MUCOUS COLITIS. In this x-ray is shown the distinctive string-like appearance of the descending portion of the lower bowel in mucous colitis, a condition frequently accompanying severe degrees of spastic or atonic colon. In the sagittal section is shown the over-secretion of mucus adhering to the bowel wall.

By providing soft, demulcent, water-retaining, mucilloid bulk, Metamucil—the "smoothage" treatment of constipation—promotes a return to normal elimination.

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

METAMUCIL® is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%), as a dispersing agent.

SEARLE *Research in the Service of Medicine*

✦ Reports and Announcements ✦

MEDICAL BROADCASTS

The subjects for health talks by Dr. Robert N. Barr, Minnesota Department of Health, from Station KUOM, Minneapolis-St. Paul, on Monday mornings at 11:15 during April and May, will be as follows:

April 4 .....Safe and unsafe water supplies
April 11 .....What can we do about cancer?
April 18.....Tuberculosis can be wiped out
April 25 .....Motherhood is safe today
May 2 .....Health for all our children
May 9 .....Minnesota's new hospitals
May 16 .....Why we need local health services
May 23 .....Accidents don't "happen"
May 30.....Health gains since the Civil War

AMERICAN ACADEMY OF NEUROLOGY

Announcement has been received of the establishment of the American Academy of Neurology, whose purpose it is to further and encourage the practice of clinical neurology and to stimulate teaching and research in neurology and allied sciences.

Active Membership in the Academy is open to every physician who has been certified in neurology or in both neurology and psychiatry. Junior Membership is available to physicians presently engaged in postgraduate studies in neurology or who are awaiting certification in neurology. In addition, there is an Associate Membership for those who are not certified in neurology but whose interests are in fields related to neurology. It is hoped that because of the unrestricted membership, this association will be representative of the entire neurological specialty and will offer an organ of expression for many of the younger men in the field. The American Academy of Neurology at present has 500 members. The first business meeting was held in Chicago in June, 1948.

The first scientific meeting will be held at the French Lick Springs Hotel, French Lick Springs, Indiana, on Wednesday, Thursday, and Friday, June 1, 2, and 3, 1949. Dr. Dave B. Ruskin of the Caro State Hospital, Caro, Michigan, is in charge of the scientific program.

The present executive council consists of Dr. A. B. Baker, Minneapolis, president; Dr. Pearce Bailey, Washington, D. C., vice president; Dr. Joe R. Brown, Minneapolis, secretary-treasurer; Dr. Frederic Lewey, Philadelphia, Dr. William A. Smith, Atlanta, Dr. J. M. Nielsen, Los Angeles, and Dr. A. L. Sahs, Iowa, Board of Trustees. Communications to the Academy should be addressed to Dr. Joe R. Brown, 19 Millard Hall, University of Minnesota, Minneapolis 14, Minnesota.

AMERICAN ASSOCIATION OF RAILWAY SURGEONS

The Sixty-First Annual Meeting of the American Association of Railway Surgeons will be held at the Drake Hotel, Chicago, Illinois, on June 30—July 2, 1949.

An exceptionally interesting and instructive scientific program has been arranged: The morning sessions will include twelve papers on various medical and surgical subjects, given by outstanding authorities. The two afternoon sessions will be devoted to symposia on "Lesions of the Bones and Joints" and "Intra-thoracic Disorders."

There will be a technical exhibit in conjunction with the scientific meetings.

The annual dinner will be held at the Drake Hotel on Friday evening, July 1, 1949.

Room reservations may be made at the Drake Hotel or at the nearby Knickerbocker Hotel.

AMERICAN BOARD OF PREVENTIVE MEDICINE AND PUBLIC HEALTH

Another specialty board, the American Board of Preventive Medicine and Public Health, approved by the Advisory Board for Medical Specialties and by the Council on Medical Education and Hospitals of the AMA, has been established and is prepared to accept applications for examinations for certification in this specialty.

In addition to the possession of an M.D. degree and a license to practice medicine, applicants must have had special training and experience in preventive medicine and public health for six years following internship.

Provision in the membership rôle has been made for a Founders Group to be composed of those who have held positions of eminence and responsibility in the field for ten years or more. No examinations will be required for Founder membership.

Further details regarding membership may be obtained from Dr. Ernest L. Stebbins, Secretary, 615 North Wolfe Street, Baltimore 5, Maryland.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The Board of Examiners of the American College of Chest Physicians announces that the next oral and written examinations for Fellowship will be held in Atlantic City, June 2, 1949. Candidates for Fellowship in the College who would like to take the examinations should contact the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

The fifteenth annual meeting of the American College of Chest Physicians will be held at the Ambassador Hotel, Atlantic City, June 2-5, 1949. An interesting scientific program has been arranged for this meeting, and speakers from several other countries are scheduled to appear.

THE AMERICAN CONGRESS OF PHYSICAL MEDICINE

The American Congress of Physical Medicine will hold its twenty-seventh annual scientific and clinical session September 6, 7, 8, 9 and 10, 1949, inclusive, at the Netherland Plaza Hotel, Cincinnati, Ohio. Scientific and

AMERICAN CONGRESS OF PHYSICAL MEDICINE

(Continued from Page 416)

clinical sessions will be given on the days of September 6, 7, 8, 9 and 10, 1949. All sessions will be open to members of the medical profession in good standing with the American Medical Association.

In addition to the scientific sessions, the annual instruction courses will be held September 6, 7, 8 and 9. These courses will be offered in two groups. One set of ten lectures will consist of basic subjects and attendance will be limited to physicians. One set of ten lectures will be more general in character and will be open to physicians as well as to physical therapy technicians who are registered with the American Registry of Physical Therapy Technicians.

Full information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE

The Cook County Graduate School of Medicine of Chicago has arranged two courses that will be of special interest to some of the members of the Minnesota State Medical Association.

A two weeks' intensive personal course in the "Diagnosis and Treatment of Congenital Malformations of the Heart" will be offered by Benjamin M. Gasul, M.D., starting Monday, June 13.

A two weeks' intensive personal course in "Cerebral Palsy" will be offered by M. A. Perlstein, M.D., starting Monday, August 1.

Dr. Gasul and Dr. Peterson are members of the attending staff of the Cook County Hospital.

NORTHWESTERN MEDICAL ASSOCIATION

An organization of skiing physicians, the first of its kind in the world, has been formed at Sun Valley.

A group of forty-five medical men from all parts of the United States, many of them outstanding in their specialties, have banded together under the name of the Northwestern Medical Association, primarily to study winter sports from the medical viewpoint. They will meet each year at Sun Valley.

Devoted to the study of skiing safety, snow blindness, high altitude and winter diseases, the physicians came together at first socially. This year, under the leadership of Dr. L. Henry Garland, San Francisco, they organized for extracurricular study.

Dr. Vern D. Smith, of St. Paul, was named secretary-treasurer at the first meeting, and Dr. John Hochfilzer, also of St. Paul, was elected to the executive committee.

The major function of the group will be that of an advisory council, and recommendations will be made in connection with all safety aspects of skiing. Dentists and allied scientists are associated members.

Dr. Richard H. Hempstead, of Rochester, is among the three Minnesota physicians who are charter members of the group.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

At the March meeting of the Minnesota Society of Neurology and Psychiatry, held at the Town and Country Club, St. Paul, Dr. Roger W. Howell, Minneapolis, lectured on "Manic Depressive Reactions." Dr. Joe R. Brown, also of Minneapolis, spoke on "The Treatment of Cerebellar Ataxia"; and Dr. J. C. Michael spoke on "Psychiatry and Law; one recent experience."

KENNY FOUNDATION AND INSTITUTE

Dr. E. J. Huenekens, chief of staff at Sister Elizabeth Kenny Institute and clinical professor of pediatrics at University of Minnesota, has been appointed national medical director of the Kenny Foundation, it has been announced by Donald C. Dayton, Foundation president.

In his new position with the Foundation, Dr. Huenekens will be in contact with medical leaders throughout the country with the aim of creating broader understanding of the Kenny concept and treatment of poliomyelitis.

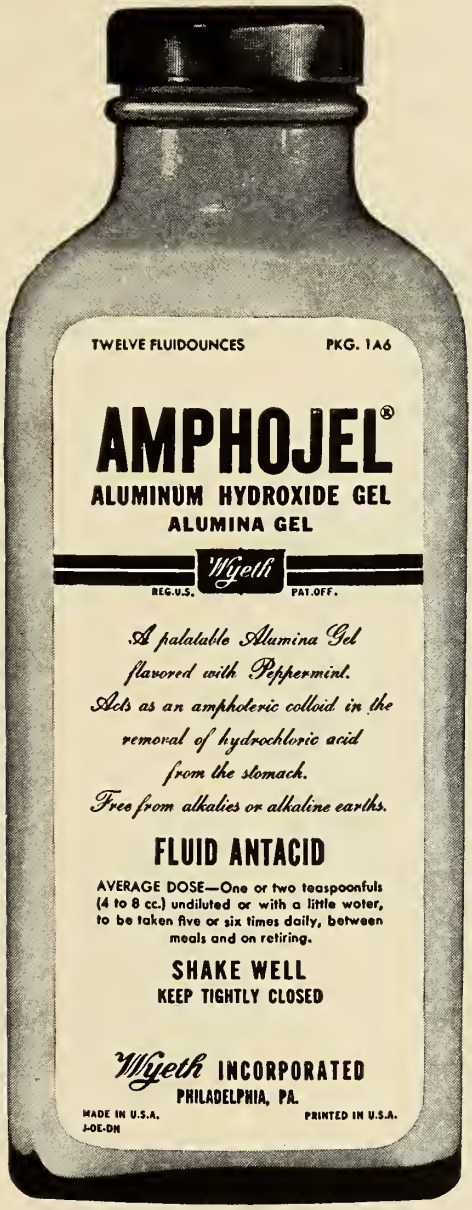
Mr. Dayton also announced that Dr. Wallace H. Cole of St. Paul, director of the division of orthopedic surgery of University of Minnesota medical school, has accepted the position of consulting orthopedist on the Kenny Institute staff.

Dr. Cole was one of three medical men who originally observed the work of Sister Kenny when she first came to Minneapolis in 1940, and his announced affiliation with the Institute renews close association with the other two, who are presently members of the staff.

They are Dr. Miland E. Knapp, chief of physical medicine in charge of training and treatment, and Dr. John F. Pohl, orthopedic consultant.

Dr. Knapp is a former president of the American Congress of Physical Medicine and former chief of staff at St. Barnabas Hospital. He is associate clinical professor of physical medicine at University of Minnesota.

Dr. Pohl is former medical supervisor at Kenny Institute.



FUNDS FOR MEDICAL RESEARCH BEQUEATHED TO UNIVERSITY OF MINNESOTA

The University of Minnesota has been named recipient of a gift of approximately one-half million dollars which is to be used for medical research. The gift comes from the estate of Mr. Silas McClure, a Minneapolis businessman who died February 16, at the age of eighty-three. Previously Mr. McClure granted funds to the University in memory of his wife, Katherine Esgen McClure.

President J. L. Morrill, expressing the University's gratitude, said, "The very generous bequest provided by Mr. Silas McClure is further evidence of the general acceptance of the high professional competence of University scientists. The University is profoundly grateful."

Dr. Harold S. Diehl, dean of medical sciences at the University, said further, "Medical and health problems of vital importance need intensive study. The facilities for such studies will be provided by the Mayo Memorial and the Variety Club Heart Hospital. . . . An unrestricted fund for medical research, such as Mr. McClure has made available, will be particularly valuable. It can be

(Continued on Page 420)

IN THE MEDICAL MANAGEMENT OF PEPTIC ULCER

FUNDS FOR MEDICAL RESEARCH

(Continued from Page 418)

used for the purchase of needed scientific equipment or to provide the technical assistance and supplies. . . . Mr. McClure's generous bequest will be used to underwrite such prospecting in better health for the people, not only of Minnesota but of the world."

CONTINUATION COURSES AT MINNESOTA

The Department of Postgraduate Medical Education, University of Minnesota, announces a continuation course in Surgery for general physicians to be held at the Center for Continuation Study May 9-10-11. The course will be made up of symposia on the following subjects: varicose veins, diagnosis and management of thrombophlebitis and phlebothrombosis, diagnosis in urological conditions and a clinic on fractures.

A continuation course in General Medicine will be held at the Center for Continuation Study May 12-13-14. The course will be devoted to lectures and clinics on Hematology and Allergy. Particular emphasis will be placed on methods of diagnosis and treatment of the various allergic states.

A continuation course in Dermatology for general physicians is scheduled at the Center for Continuation Study for May 26 and 27. The course will be devoted to the diagnosis and management of the common skin disorders.

NATIONAL SOCIETY FOR CRIPPLED CHILDREN AND ADULTS

The annual convention of the National Society for Crippled Children and Adults will be held November 7, 8 and 9 at the Commodore Hotel, New York, according to an announcement made from Chicago headquarters by Lawrence J. Linck, executive director.

Prominent authorities working in the field of the handicapped will present latest developments at the three-day session marking twenty-eight years of service for the Society.

Delegates from 2,000 state and local affiliates of the National Society will discuss research, rehabilitation, training and treatment for the handicapped.

NU SIGMA NU BANQUET

The annual banquet of Nu Sigma Nu medical fraternity will be held Saturday, April 30, 1949, at the Minnesota Club in Saint Paul. Cocktails will be served at 5:30 o'clock, with dinner at 7:30 sharp.

Dr. Stewart Graves, executive secretary of Nu Sigma Nu and dean of the Medical School of the University of Alabama, Tuscaloosa, will be guest of honor. Dr. Archie Beard, Minneapolis, member of the National Board, will also be present. A brief report on the activities of alumni will be given by Dr. Wm. A. Hanson, Minneapolis, and on the activities of the local Active chapter by Dick Sells. Dr. Graves will give a brief address.

A room has been reserved for those who wish to remain following the dinner to play cards.

Reservations should be made by April 26 through Dr. Charles N. Hensel, 613 Lowry Medical Arts Bldg., Saint Paul 2, Minnesota. Check for tickets, at $7.50, should accompany request for reservation.

HENNEPIN COUNTY MEDICAL SOCIETY

At the regular March meeting, members of the Hennepin County Medical Society took an affirmative vote on the AMA assessment plan. Dr. Ralph Creighton, acting chairman of the Board of Directors, and Mr. Thomas P. Cook, newly elected executive secretary, spoke before the group.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

A preliminary meeting of the Northern Minnesota Medical Association was held recently in Alexandria where an outline was planned for a meeting to be held on September 9 and 10, 1949, in the city of Alexandria. A general program committee was selected, tentatively including Dr. C. L. Oppegaard of Crookston, Minnesota, Mr. C. C. Carlson of Alexandria, Minnesota, Dr. Clarence Jacobson of Chisholm and Dr. W. B. Coventry of Duluth. Dr. L. F. Wassom of Alexandria is the general chairman in charge of local arrangements.

The twenty-ninth annual meeting will have a varied program of interest to the general practitioner, covering the fields of general medicine, general surgery, obstetrics, gynecology and specialties. An evening banquet on September 9, 1949, will feature a noted guest speaker. The Park Region Medical Society is host, and it is expected that this will be an unusually interesting meeting.

RAMSEY COUNTY MEDICAL SOCIETY

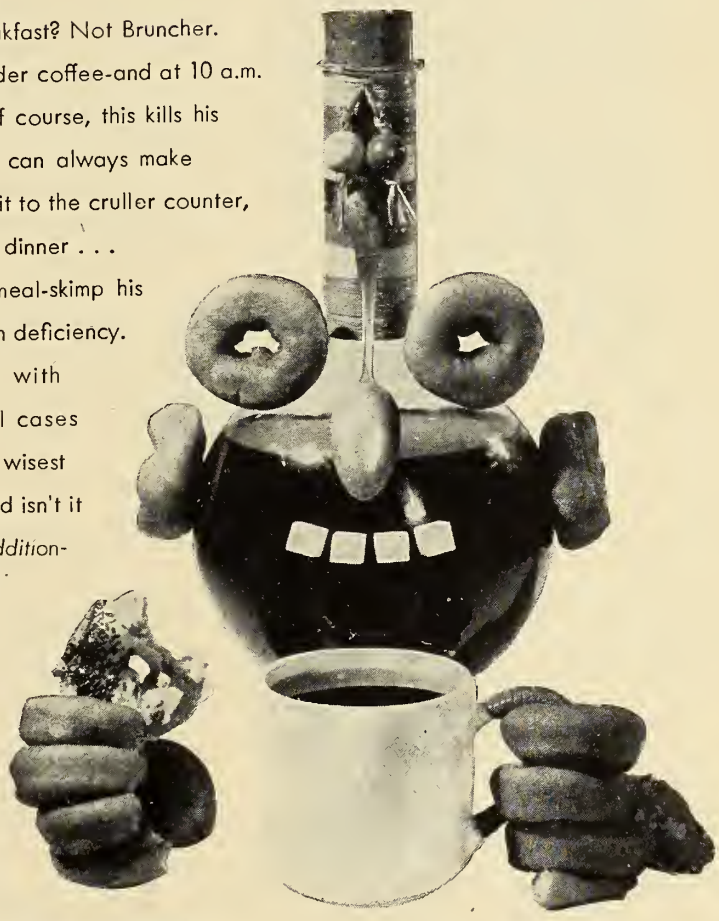
Two hundred fifty physicians attended the monthly meeting of the Ramsey County Medical Society which took place on the last day of February. Discussion that evening was concerned with the compulsory health insurance plan, the AMA $25 assessment and educational plan, and the Oscar Ewing Report. Five physicians spoke to the group: Dr. B. B. Souster, Dr. Ernest M. Hammes, president of the Minnesota State Medical Association, Dr. George Earl, Dr. Olof I. Sohlberg, and Dr. E. J. Fogelberg, all of St. Paul.

ST. LOUIS COUNTY MEDICAL SOCIETY

At the regular monthly meeting of the St. Louis County Medical Society held on March 10 at St. Mary's Hospital, Duluth, the attending physicians voted approval of the AMA 12-point medical and public health advancement program. Speaking to the gathering was Dr. A. O. Swenson who favors the voluntary health programs. Citing statistics, he said that some 52,000,000 Americans are now members of privately owned health insurance groups, and that the public can look forward to better coverage as memberships grow.

PHYSICIAN-ARTISTS, BEWARE!

Those planning to exhibit at the Atlantic City Exhibition (American Medical Association, June 6-10, 1949) are requested to note that—NOW is the time to write for entry blanks, rules, shipping labels, et cetera.



Haste is necessary, because entries must reach Atlantic City between April 15 and May 9.

For details, write airmail to Francis H. Redewill, M.D., Secretary, American Physicians Art Association, Flood Building, San Francisco, California.

MR. BRUNCHER IS A DONUT-MUNCHER

Skip breakfast? Not Bruncher.

Not if you consider coffee-and at 10 a.m. as breakfast, that is. Of course, this kills his appetite for lunch, but he can always make that up by an afternoon visit to the cruller counter, which kills his appetite for dinner . . . And thus does Bruncher meal-skimp his way to a subclinical vitamin deficiency.

Your own experience with these half-sick, half-well cases indicates that the first and wisest move is dietary reform. And isn't it also wise to prescribe, *additionally*, a vitamin supplement —to assure adequate intake just in case a patient strays from the prescribed diet?

For your prescribing convenience, there's an Abbott vitamin product to answer nearly every vitamin need— for supplementary or therapeutic levels of dosage, for oral or parenteral administration. All are rigidly standardized to conform with label listings. They are available at pharmacies everywhere.

SECOND SOUTHWESTERN HEALTH DAY DRAWS 1,200

Mrs. W. G. Benjamin

The second Southwestern Minnesota Health Day program was held in Pipestone at the High School Auditorium, February 22, and was one of the most outstanding health events ever held in this city or in southwestern Minnesota. More than 1,200 people gathered to hear eminent physicians and educators discuss some of the more important local health problems of today.

Since the first Health Day, which was held at Worthington in February last year, there have been five such events throughout the state at Willmar, Fergus Falls, Crookston, Mankato and Duluth.

Health Day programs are presented as a means of creating interest among the people of the state in common health problems and educating them in ways of improving personal and public health conditions. Physicians and educators have been willing to give liberally of their time and talent in promoting these projects. Interest was activated in this district by having some 200 organizations in the eight counties (Pipestone, Rock, Murray, Nobles, Cottonwood, Jackson, Lyon and Lincoln) co-sponsor Health Day, each organization giving suggestions for the program, and having a representative on the organization committee.

Many of the speakers at the meeting suggested the extension of local health services as a means of promoting better health conditions in the community. They also urged the formation of district mental health facilities and county health councils. They pointed out that these objectives may be accomplished only when all the people in a community become interested and work together for a common cause.

Twenty educational health booths and exhibits were a new and interesting feature of this Health Day. Trained personnel, representing the various health groups in the state, presented educational exhibits, showed health movies, dispensed literature, and were on hand to give information to the visitors.

The program began at nine o'clock with the local Auxiliary members acting as hostesses and nine high school students assisting with registration. Mrs. Walter G. Benjamin, Southwestern Minnesota Auxiliary president, gave the address of welcome. More than 600 people attended the morning session on mental health.

During the noon hour, through the courtesy of the city of Pipestone, a free lunch was served to all who were present.

The afternoon program opened with a panel on safety. This was followed by another panel on "Trouble Shooting Your Health Problems," and closed with the showing of health movies.

The evening session opened with a short concert by the Pipestone High School band. Mrs. Harold Wahlquist of Minneapolis, state president of the Woman's Auxiliary, gave a review of Health Days, for which she was well qualified, having been present at all the Health Day programs. Dr. Henry F. Helmholz, of the Mayo Clinic, of Rochester, was the principal speaker on the evening program. He told of existing conditions, and what is being done for the children in the devastated countries of Europe.

NEW OFFICERS FOR FREEBORN COUNTY

Mrs. Robert A. Demo is the new president of the Freeborn County Medical Auxiliary. Other officers are: Mrs. L. C. Barr, vice president; and Mrs. H. B. Neel, secretary-treasurer. All three officers are from Albert Lea.

RAMSEY TO ENTERTAIN AUXILIARIES, MAY 9-11

Mrs. W. H. Von der Weyer

Two luncheons, a style show, dramatic entertainment, a tea and a breakfast have been arranged by the Ramsey County Auxiliary for wives of physicians attending the annual Minnesota State Medical Association meeting in Saint Paul, May 9, 10 and 11.

The first luncheon will be in the Casino Room of the Hotel Saint Paul, following the Executive Board meeting Monday, May 9. At 3 p.m. there will be a tea in the lounge of the Women's City Club honoring State Auxiliary officers. That evening, in the Continental Room of the Hotel Saint Paul, there will be a variety program, including singing, motion pictures and dancing, and the Hennepin County Auxiliary will present a skit entitled, "Episodes in the Life of a Doctor's Wife."

The annual meeting of the State Auxiliary will be held at the Minnesota Club at 10:00, followed by the annual luncheon, featuring a style show.

Physicians and their wives will attend the annual Medical Association banquet Tuesday evening, and Auxiliary members will have a final conclave Wednesday morning at a 10 o'clock breakfast at the Hotel Saint Paul.

CANCER ACTIVITIES VARIED

Mrs. Mark E. Ryan

The State Auxiliary, following a twelve-month calendar of public health projects, is turning its attention to cancer during April by taking stock of what has already been done and what new activities can be started.

For many years, the Auxiliary has been affiliated with the Minnesota Division of the American Cancer Society. The Auxiliary Executive Board includes a Cancer Committee chairman who keeps the Auxiliary informed of the work being done by the Cancer Society and its need for assistance.

The state-wide poster-essay contest on cancer, which is annually sponsored by the Minnesota Division of the American Cancer Society and the Woman's Auxiliary to the Minnesota State Medical Association, has just been completed. More than 12,000 children participated,

POUR DIRT AWAY with Rexair

Wouldn't you like to get rid of dusty vacuum bags forever? Wouldn't you like to pour dust away as easily as dirty dishwater?

You can, with Rexair—the amazing new home appliance that washes your dust away. Rexair collects dust in water; you just pour the water down the drain and flush—dust and dirt go with it.

When you clean with Rexair, you clean *clean*. Rexair has no porous bag through which dust can escape back into the air you breathe. Instead, the air passes through a churning bath of water which wets down the dust and returns only dust-free air to the room. Wet dust cannot fly, and dust cannot escape from Rexair's water basin.

Rexair washes the air in your home, humidifies, vaporizes medicaments, even scrubs floors. See the Rexair before you buy a humidifier, a vaporizer, or even a vacuum cleaner. Over 1,000,000 in use.

FREE BOOK: Send for this free, illustrated 12-page book. Shows how Rexair even cleans the air you breathe. REXAIR DIVISION, MARTIN-PARRY CORP. Box 964, Toledo 1, Ohio, Dept. L-49

Rexair

MAY-O-LITE Helps Solve Reflection Problem

As you know, surfaces of glasses reflect light. This in turn produces out-of-focus "ghost images." These reflections interfere with the transmitted image light, reduce definition and contribute to eye strain.

Usually this is considered the normal burden of a person who wears glasses. This need no longer be so. By application of our Low Reflection Lens Coating, most of these out-of-focus "ghost images" are converted into transmitted light, providing more transparent glass.

Let's see what this amounts to.

Our Low Reflection Lens Coating,

1. Reduces out-of-focus surface reflections up to as much as 95 per cent.
2. Improves image definition.
3. Increases transmission of light—more transparent glass.
4. Hardens the lens surfaces—reducing surface scratching.
5. Provides better vision—less eye strain.

Developed for the armed services during the war as a means to improve image definition in military instruments, our Low Reflection Lens Coating is now available to your patients.

Explain this revolutionary new process to your next patient! It is available through most manufacturing and dispensing opticians. Write for descriptive pamphlet and coated sample of glass, today.

CANCER ACTIVITIES VARIED

(Continued from Page 422)

indicating the interest which this type of cancer education has stimulated.

Many Auxiliary members attended the cancer school for lay people held at the University's Center for Continuation Study, February 18 and 19. The course is conducted by the State Cancer Society to educate its corps of workers in the newest developments and progress in the field of public health.

An unprecedented volume of requests for funds and dressings has accelerated County Auxiliary efforts. Many of the units are engaged in making dressings to supply county nurses who care for indigent cancer patients. Many supplies are also being channeled to Our Lady of Good Council Hospital in Saint Paul. This hospital, one of six of its kind in the United States, was opened in 1941 and has a 100-bed capacity, with four large wards. Any patient is admitted, regardless of religion, color, sex, age or place of residence. The only requirement is a written statement from the physician that the patient is incurably ill and indigent.

NURSE RECRUITMENT TEAS ON DOCKET

Mrs. Russell Hendrickson

Junior and senior high school girls will be entertained at tea in Moorhead, Barnesville, Hawley, Lake Park and Detroit Lakes by the Clay-Becker Auxiliary. A speaker at each tea will supply information concerning the various types of nursing services and their training requirements.

This is the second project undertaken recently by the Clay-Becker Auxiliary. Members held a sale at Detroit Lakes of articles made by patients of Sand Beach Sanatorium. They plan next year to expand the sale, which is an annual event, to neighboring cities.

ANNUAL AMA AUXILIARY MEETING, JUNE 6-10

Haddon Hall will be the headquarters for the annual meeting of the Woman's Auxiliary to the American Medical Association, scheduled for Atlantic City, New Jersey, June 6-10.

Requests for reservations are to be sent to Dr. Robert A. Bradley, Chairman, Subcommittee on Hotels, 16 Central Pier, Atlantic City, New Jersey.

O'BRIEN MEMORIAL PLANS COMPLETED

Mrs. Harlow Hanson

Over a period of years, the Woman's Auxiliary to the Minnesota State Medical Association has been actively interested in health education. For counsel and guidance, members frequently turned to Dr. William A. O'Brien. No matter how rushed he was in his busy daily life, he always found time, not only to give valued suggestions, but to contribute appreciably to the success of Auxiliary programs throughout the state with his unforgettable health talks. His fund of information seemed inexhaustible, and his own special way of reaching the public with his message inspired a keener interest in public and personal health.

In appreciation of Dr. O'Brien's unceasing interest, a memorial fund is being established by the members of the State Medical Auxiliary. A desk and chair will be placed in his honor in the Dr. O'Brien Memorial Seminar room in the Mayo Memorial building, at the University of Minnesota.

MIDWINTER BOARD MEETING

Mrs. W. A. Merrit

Forty Auxiliary members met at the Continuation Center of the University of Minnesota, February 24, for the mid-winter meeting of the board of directors and heard Mrs. H. F. Wahlquist, state president, report on the Chicago conferences of November 4 and 5.

Special reference was made to discussions on school health, the Ewing report and the facilities of the National Physicians Committee and the American Medical Association.

The president-elect, Mrs. H. E. Bakkila, reviewed scholarship fund procedure and commented on the hospitality proffered to guests at the Chicago conference.

Mrs. Mark Ryan reported a two-day cancer school, stressing a threefold program: service, research and education.

Mrs. Benjamin Souster, Auxiliary editor for MINNESOTA MEDICINE, thanked the journal for the space given the Auxiliary and urged auxiliaries to send material to her, or to the office of the Minnesota State Medical Association.

Mrs. C. L. Sheedy outlined methods of selling *Hygeia* and reported an increase in subscriptions over last year. Mrs. Bakkila announced that Clay-Becker and McLeod Counties have reorganized.

Mrs. Hubert Johnson's public relations report on Health Days held in Worthington, Willmar, Fergus Falls, Crookston, Duluth, Mankato, Pipestone, Minneapolis and Saint Paul was amplified by William Griffiths of the Minnesota Department of Health. Mr. Griffiths gave credit to the Auxiliary and its president for introducing the program in Minnesota. "The approach through education is best," he pointed out. "Laws are ineffective until people are ready for them. The educational process is a slow process; people are not enlightened overnight."

He added that Health Days—and the Health Councils that are developing from them—are a direct answer to Mr. Ewing. "They are the democratic way of doing things."

The National Health Assembly, held in Washington, D. C., in February, was reviewed by Dr. F. J. Elias. After describing briefly the AMA's co-ordinating committee of fifty-three members and the work being done by the public relations counsel of Whitaker and Baxter, he told the women that the first job ahead is defeating, within the next sixty days, the Wagner-Murray-Dingell Bill. "Secondly, we must develop a long-term program so we can completely destroy compulsory health insurance—by educating the public to the issues involved and by taking the financial shock out of illness through encouragement of voluntary insurance plans," he said.

Mrs. Elmer Rusten, legislative chairman, cited the

With one self-contained, easily operated instrument, every otologist can now make EVERY known hearing test, no matter how complex. Each is made with unprecedented precision. That was the concensus of many practicing otologists as well as university and hearing clinic researchers at the recent Academy meeting in Chicago.

The new instrument is the E-1 Audiometer developed by MAICO, suppliers of 90% of the precision audiometers used in America. One doctor, prominent for research in hearing acuity, commented that the facilities were almost as complete as he had in his $18,000 laboratory.

With the E-1 Audiometer, thorough testing of every type becomes easily attained. Every day, in countless new ways, it is found to fit individual practice requirements. Your local MAICO distributor can present a personal demonstration. Or write to the address below to learn how complex tests can be made so convenient.

In Memoriam

GILBERT COTTAM

Dr. Gilbert Cottam, former Minneapolis doctor and leader in Minnesota and South Dakota medicine, died Friday, March 4, 1949, in Pierre, South Dakota, at the age of seventy-five.

A well-known surgeon and medical spokesman, Dr. Cottam left Minneapolis in 1940 to practice in Sioux Falls, S. D. He became superintendent of the South Dakota State Board of Health, at Pierre, in 1943.

Dr. Cottam was born in Manchester, England, and came to the United States at the age of sixteen.

He was graduated from St. Louis (Mo.) University in 1893, practiced at Rock Rapids, Iowa, until 1910, at Sioux Falls until 1930, and then for ten years in Minneapolis.

At various times he was president of the South Dakota State Medical Association, a governor of the American College of Surgeons, president of the Sioux Valley Medical Association, associate editor of MINNESOTA MEDICINE and editorial board member of *Journal-Lancet*.

In the Hennepin County Medical Society, he was a trustee and executive committee member and editor of *The Bulletin*.

Dr. Cottam was a leader in the movement "to provide the public with information as to who is a specialist and who is not," and in 1927 became one of the founders of the American Board of Surgery.

During World War I, he was a major in the army medical corps and surgical chief at the 88th base hospital in France. In World War II, he headed emergency medical service at the Sioux Falls Office of Civilian Defense.

He wrote many scientific papers and held many medical posts.

BYRON O. MORK, SR.

Dr. B. O. Mork, Sr., dean of the southwestern Minnesota medical profession and one of the founders of the Worthington Clinic, died March 2, 1949, at the age of eighty-two.

Byron Olaf Mork was born in Hjorundford near Aalesund, Norway, March 28, 1867. As a lad of nineteen, he came to the United States in 1866, worked several years with an Indian agency at Granite Falls and on farms before entering Hamline University, where he qualified for his bachelor's degree in 1898.

It was early in the first decade of the present century that Dr. Mork gained his M.D., at Hamline, at the age of forty.

After about a year in Hills, Dr. Mork moved to Worthington in 1908, to remain the rest of his life, to round out forty years in the practice of his profession.

His first associate in medical circles was Dr. Henry Wiedow, with whom he operated the old City Hospital. In 1918, Dr. Mork entered partnership with Dr. F. G. Watson of Rushmore, and Dr. G. C. Turner.

In 1920 the three partners were joined by three others —Drs. F. W. Metcalf and C. R. Stanley, Fulda, and Dr. J. T. Smallwood, Worthington, in formation of the Worthington Clinic.

Dr. Mork was married in 1899 at Wood Lake to Maude Coghlan, mother of his three children: Elmer, who died during the 1918 influenza epidemic; Byron O. Jr., now a clinic staff physician, and Raymond E., present Nobles County attorney. Mrs. Mork died in 1940. He was married in 1942 to Mrs. Metcalf, widow of his former associate, who also survives him. There are three grandchildren.

ANGUS W. MORRISON

Dr. Angus W. Morrison, prominent in Minneapolis medical and civic affairs for thirty-five years, died January 28, 1949, at Eitel Hospital. He was sixty-five years old.

Dr. Morrison was a member of a pioneer Minneapolis family. His grandfather, Dorilus Morrison, was the city's first mayor in 1867, and was associated with many of the early industries.

Dr. Morrison was one of the founders of the Nicollet Clinic.

For several years he was a member of the staff at the University of Minnesota Medical School, and for many years a member of the staff at General Hospital.

He was a member of the American Neurological Society, American Psychiatric Society, American Medical Association and other medical organizations. He served as a captain in the medical corps of the United States Army in France in World War I.

Retiring from an active practice of medicine in 1931, Dr. Morrison became prominently identified in the business life of his city.

Dr. Morrison was born in Minneapolis July 18, 1883, the son of Clinton and Julia Washburn Morrison. He lived his entire life in the Twin Cities area. His home at his death was at Maplewoods, Wayzata.

He was educated in Minneapolis schools; Hotchkiss school, Lakeville, Conn.; Yale University, and Johns Hopkins Medical School.

He took postgraduate work in Munich, Berlin and London and served an internship at the Royal Victoria Hospital, Montreal, Canada. He started the practice of medicine in Minneapolis in 1912, specializing in neurology and psychiatry.

In 1914, Dr. Morrison was married to Helen Truesdale, and she survives him. Other survivors include a daughter, Mrs. John P. Snyder, Jr.; three sons, Clinton, Angus and John; and five grandchildren, all of Wayzata.

G. ALLEN SATHER

Dr. G. Allen Sather, practicing physician in Fosston, Minnesota, for forty years, died at his home in Fosston, February 14, 1949, at the age of sixty-eight.

Dr. Sather was born August 15, 1881, at Cannon Falls, and lived at Willmar. His medical training was received at the University of Iowa, from which he received the M.D. degree in 1908. He practiced medicine for a short time at Ridgeway, Iowa, and was married there to Clara Mathilda Ringoen in 1909. That year they moved to Fosston.

In addition to his medical practice, Dr. Sather was mayor of Fosston for several terms, a director of the Farmers State Bank and once president of the board. He was a member of the Red River Valley Medical Society; the Minnesota State Medical Association and the American Medical Association.

Dr. Sather was preceded in death by his wife who died December 12, 1948.

Survivors include four sons and one daughter: Dr. George Sather, Fosston; Dr. Norman Sather, Mora; Dr. Edgar Leland Sather, Flatrock, Michigan; Dr. Andrew Sather, Bemidji, and Mrs. Luther Moore, Lexington, Kentucky.

He is also survived by his sister, Mrs. Helen Riemen, Glencoe; and three brothers: O. P. Sather, Minneapolis; Dr. Edgar Sather, Alexandria; and Frank Sather, Minneapolis.

HERBERT P. SAWYER

Dr. H. P. Sawyer, resident of Goodhue, Minnesota, for forty-four years, died on the morning of March 10, 1949, in a Red Wing hospital. He had been in failing health for several years.

Born in Steele County, November 25, 1870, Dr. Sawyer attended country schools, graduating from the Owatonna high school in 1899. The following two years he taught school, then attended the medical department of the University of Minnesota in 1901. Following his graduation, he began practice in Goodhue village in 1905 and continued in active practice until 1931 when he retired.

During his practice in Goodhue, Dr. Sawyer was associated at various times with Drs. C. E. Gates, S. V. Gausemal and George Dewey. His marriage to Miss Minora Backman took place in Goodhue in 1920.

Survivors include his wife, one sister-in-law, Mrs. G. A. Sawyer of Minneapolis, and one niece, Margaret, also of Minneapolis.

ROY G. SPURBECK

Dr. Roy G. Spurbeck, widely known Cloquet physician, died at his home on February 12, 1949. He had been in ill health a number of years.

Born in Mantorville, Dr. Spurbeck moved with his parents to Two Harbors as a boy, residing there several years. He was a graduate of Northwestern University medical school. He practiced medicine at Proctor for a couple of years and in 1917 came to Cloquet, continuing until poor health forced his retirement.

Dr. Spurbeck was a member of the Minnesota State Medical Association, the St. Louis County Medical Society, Dallas lodge, local Masonic Order, and of the Scottish Rite, Duluth Masonic Chapter.

He is survived by his widow, Ruby, Cloquet; a son, Dr. George Spurbeck, Menominee, Wisconsin; a daughter, Mrs. Sherman Borsheim, Duluth, and two grandchildren.

WOMAN'S AUXILIARY

Midwinter Board Meeting

need for speakers and listed material that would be valuable to them. Mrs. W. H. Von der Weyer, chairman of the Committee on Arrangements for the annual meeting, extended an invitation to the functions being planned for the entertainment of members and visitors at the annual meeting in Saint Paul, May 9, 10 and 11.

HENNEPIN DISCUSSES COMMUNITY HEALTH

Mrs. R. F. Erickson

Hennepin County Health Day, March 4, centered around a panel discussion of "A Successful Health Program Needs Community Support."

Dr. Gaylord Anderson, head of the Public Health Department of the University of Minnesota, moderated the discussion. Panel members were: Dr. Clare Gates, city health department; Dr. Hermina Hartig, school health department; Mrs. Ruth T. Devney, director of community information; Calvin Aurand and Mrs. John C. Benson, health action committee; Dr. Charles Merkert, chairman of the public health committee of the Hennepin County Medical Society; Ann Hauser, county nursing service; George E. Johnson, alderman from the eighth ward and member of the health and hospitals committee of the Minneapolis Council.

Movies on cancer, mental hygiene and accidents were shown during the noon hour, with commentary by Mrs. Netta Wilson of the Minnesota Department of Health.

During the afternoon session, Dr. Robert McGandy spoke on "Trends in the Practice of Medicine," and Gov. Luther W. Youngdahl presented his proposed mental hygiene program for the state.

The next project of the Hennepin County Auxiliary is a benefit luncheon and style show, April 18. Tickets, at $2.50, may be obtained by writing or calling Mrs. Donald MacKinnon, 4000 W. 24th Street, Whittier 4457, or by writing the Hennepin County Medical Auxiliary, 2000 Medical Arts Building, Minneapolis.

"Town Meeting" in Rochester

"America's Town Meeting" will present a broadcast on Tuesday, April 26, in connection with National Mental Health Week. The topic will be "How Can We Find Personal Peace and Security in Today's World?" and the broadcast will take place from the Arena in Rochester, Minnesota.

MINNESOTA STATE MEDICAL ASSOCIATION

96th ANNUAL MEETING SAINT PAUL—MAY 9-11

(Continued from Page 430)

Dr. Manley F. Juergens, formerly of Minneapolis, has joined the staff of the Johnson-Haberle Clinic in Thief River Falls, where he is specializing in the practice of internal medicine and roentgenology.

* * *

Dr. Robert L. Nelson of Duluth attended the Chicago Medical Society Clinical Conference in Chicago during March. Also attending were Dr. L. W. Johnsrud and Dr. F. W. Bachnick of Hibbing. The meeting was held at the Palmer House.

* * *

Dr. and Mrs. Byron Kinkade, originally of Caledonia, now residents of Minot, North Dakota, returned home for a visit in February to visit Rev. and Mrs. R. L. Kinkade. From Caledonia, they traveled to Ohio, visiting the parents of Mrs. Kinkade.

* * *

Dr. J. R. McDonald of Rochester presented two papers during February in Minneapolis, giving a Kellogg Lecture on "The Pathology of Bone Tumors"; and to the Minnesota Pathological Society, a paper: "The Smear Technic as an Aid in the Diagnosis of Cancer."

* * *

The son of the late Dr. J. J. Donovan of Litchfield, Dr. Thomas Donovan of Houston, Texas, died on March 7, at the age of thirty-eight. Surviving are his wife and three children. Dr. Donovan served as a military physician in World War II.

Dr. James A. Johnson, Minneapolis, was named to judge essays in the Hennepin County state-wide essay and poster contest sponsored by the Minnesota Cancer Society.

* * *

Dr. L. F. Richdorf, clinical associate professor of pediatrics at the University of Minnesota, delivered a talk on breast and bottle feeding before physicians attending the short course on pediatrics offered at the University's Center for Continuation Study early in February.

* * *

Dr. J. R. McDonald, Rochester, speaking at the Center for Continuation Study at the University of Minnesota, in March, presented a paper entitled, "The Cytologic Examination of Body Secretions for Cancer Cells." Among state physicians attending the lecture was Dr. D. S. Branham of Albert Lea.

* * *

Dr. D. J. Erickson of the Mayo Clinic read two papers at the postgraduate course in physical medicine and rehabilitation at the University of Texas Medical Branch in Galveston, Texas, last month. They were: "Physical Medicine in Rehabilitation to Geriatrics," and "Rehabilitation of the Paraplegic."

* * *

Dr. Christopher Graham, the only surviving partner of the Mayo brothers, was the subject of a pictorial interview in the February issue of *Friend*, a General Motors

Theocalcin

Council Accepted

In Congestive Heart Failure

For the reduction of edema, to diminish dyspnoea and to strengthen heart action, prescribe Theocalcin, beginning with 2 or 3 tablets t. i. d., with meals. After relief is obtained, the comfort of the patient may be continued with smaller doses. Well tolerated.

Theocalcin, brand of theobromine-calcium salicylate, Trade Mark reg. U. S. Pat. Off.

Available in 7½ grain tablets and in powder form.

Bilhuber-Knoll Corp. Orange, N. J.

publication. Dr. Graham, who lives in Rochester, is a member of the board of directors for the Mayo Foundation.

* * *

Dr. Q. S. Baker of Rochester began the management of a neurosurgical clinic in February at the United States Army Hospital, Oliver General Hospital, in Augusta, Georgia. Recently he presented a paper to the staff on "A Clinical Appraisal of the Problem of Protruded Intervertebral Disk."

* * *

Drs. D. C. Campbell and W. D. Seybold of Rochester addressed the Chippewa County Medical Society, Chippewa Falls, Wisconsin, in February. Dr. Campbell spoke on "Newer Methods of Treating Blood Dyscrasias," while Dr. Seybold spoke on "Acute Abdominal Emergencies."

* * *

Dr. H. R. Butt of Rochester attended the Medical and Surgical Symposium, sponsored by the Watts Hospital at Durham, North Carolina, in February. Participating in a clinicopathologic conference, he presented a paper entitled "Evaluation of Current Tests for Liver Function."

* * *

Dr. Adelaide M. Johnson, psychiatric consultant for the Mayo Clinic, spoke at the annual meeting of the Family and Children's Service in Minneapolis on February 7, stressing the need for "a block of time" of reading, research and teaching in the training of social workers.

On March 9, Dr. Victor Johnson, Rochester, presented a paper to a joint meeting of the Philadelphia County Medical Society and the American College of Physicians, a meeting which marked the hundredth anniversary of the former organization. Dr. Johnson's paper was entitled, "Medical Education: The Past Century and the Future." The meeting was held in Philadelphia.

* * *

Dr. S. S. Houkum and Dr. W. A. Klein of Duluth presented a report on the annual meeting of the American Academy of Orthopedic Surgeons, held in Chicago earlier this year, to members of the St. Louis County Medical Society, at a meeting held on March 10. Speaking also before the group was Dr. Frank J. Elias who talked on pending medical legislation.

* * *

The home of the late Dr. Donald Colp, situated in Robbinsdale, has been converted into a twenty-nine-bed rest home. Dr. Edward Colp son of the late physician, is opening his offices in the new building. Modern equipment is being installed to care for the chronic, convalescent and aged patients there. The home was opened early in March.

* * *

Dr. L. F. Leitschuh, originally of Sleepy Eye, has just completed his residency at St. Mary's Hospital, Minneapolis, where he specialized in obstetrics and gynecology. He is planning to establish private practice in Minneapolis. Dr. Leitschuh's brother, Captain Robert Leitschuh, will receive his discharge from the army in

July, at which time he will accept a three-year residency at the Veterans Hospital in Milwaukee, specializing in orthopedics and general surgery.

* * *

Among those present at the University of Minnesota's Center for Continuation Study for the course in heart disease were: Dr. Sidney A. Whitson, Dr. Donald S. Branham, and Dr. Daniel L. Donovan, Albert Lea; Dr. A. J. Lenarz, Browerville; Dr. A. Neumaier, Glencoe; Dr. R. J. Wilkowske, Owatonna, and Dr. Julius C. Buscher, St. Cloud.

* * *

Dr. Reynold Jensen, who is in the pediatrics department at the University of Minnesota, spoke at the Junior Chamber of Commerce Alumni Luncheon in February, at the St. Cloud Hotel. Dr. Jensen's topic was, "Your Child's Mental Health." This talk was presented as part of St. Cloud's observance of University of Minnesota Week.

* * *

Dr. Conrad Karleen of Minneapolis spoke at the final meeting of the in-service course on conservation of human resources sponsored by the department of special education and rehabilitation, Minneapolis Public Schools. The meeting, held in Bryant Junior High School, took place on March 15. Dr. Karleen discussed reconstructive surgery with the group.

* * *

Dr. J. M.McMahon, Mayor Clinic, speaking at the Mid-Continent Regional Park and Recreation Conference, on February 25, emphasized the importance of recreation and hobbies as part of the mental health program of any individual. He described particular programs which can be community and family-wide aids. The meeting, held in Rochester, had over 100 attendants.

* * *

Dr. Deno Wedes of St. Paul has recently become associated with Dr. G. F. Engstrom, Willmar, in the practice of medicine and surgery. Dr. Wedes completed his internship at the University Hospital in Madison, Wisconsin, and shortly thereafter engaged in special studies in internal medicine at the University of Wisconsin.

* * *

Dr. O. T. Clagett of the Mayo Clinic in February, spoke in Wichita, Kansas, where he presented two papers to a joint meeting of the Sedgwich County Medical Society and the Wichita Medical Society. His first paper was entitled "Surgical Management of Lesions of the Stomach and Duodenum"; the second, "Surgical Treatment of Congenital Anomalies of Great Vessels."

* * *

Dr. J. W. Pender, Rochester, presented a talk to the Kansas Section of Anesthesiology at Emporia, Kansas, early this year, speaking on "Responsibilities of the Future Anesthesiologist." While in Kansas, he spoke to a joint meeting of the Kansas Section of Anesthesiology and the Lyon County Medical Society on "Anesthesia for Abdominal Surgery."

* * *

Dr. Albert Faulconer of Rochester lectured for a course at the George Washington University School of

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

PSYCHIATRISTS IN CHARGE
Dr. Hewitt B. Hannah
Dr. Joel C. Hultkrans

2527 2nd Ave., S., Minneapolis, Phone AT. 7369

The Birches Sanitarium, Inc.

2391 Woodland Avenue

Duluth 3, Minnesota

A hospital for the care and treatment of Nervous and Mental disorders. Quiet, cheerful environment. Specially trained personnel. Recreational and occupational therapy.

Psychiatrists in Charge
L. R. Gowan, M.D. L. E. Schneider, M.D.

Medicine, Washington, D. C., in February. The lectures presented were: "Anesthesiology: Oximeter, Gas Analysis, Blood Pressure and Flow, and So Forth," and "Oxygenation: Relation to Inhalation and Intravenous Anesthesia."

* * *

Dr. F. J. Hill, Minneapolis city health commissioner, announced in February that an additional room would be opened at the Well-Child Clinic, at Third Street and Third Avenue South, for the convenience of shoppers in the Loop area. The clinic, which opened on February 21, 1949, will be in operation on both Mondays and Fridays.

* * *

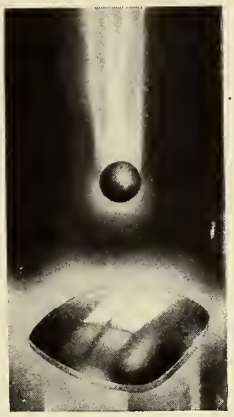
Dr. Leo F. Twiggs, originally of Benham, Kentucky, moved in February to Austin where he is associated in practice with Dr. Paul Leck. Dr. Twiggs is a graduate of the University of Michigan Medical School, 1941. His internship was served at the Henry Ford Hospital in Detroit, following which he entered the armed services.

* * *

Dr. J. K. Butler of Carlton visited Chicago in February to attend the fourth annual meeting of the National Conference on Rural Health and the National Conference on Medical Service. Dr. Butler acted in the capacity of a delegate from the seventh Minnesota district. Later that month, Dr. Butler attended the course on cardiovascular diseases at the University of Minnesota's Center for Continuation Study.

* * *

Recently appointed to head the department of pediatrics at Stanford University was Dr. John A. Anderson of Minneapolis. Dr. Anderson's new assignment will begin in September of this year. Formerly Dr. Anderson served as chairman of the Pediatrics Department of the University of Utah; and from 1937 to 1943, as a member of the faculty at the University of Minnesota Medical School, of which he is a graduate.



* * *

At a meeting of the Central Surgical Association held in Cleveland, Ohio, in February, two physicians from Rochester delivered papers. Dr. E. S. Judd presented a paper written in collaboration with Dr. L. H. Beahrs: "Epithelioma of the Lower Lip: Evaluation of the Cervical Lymph Node Dissection." Dr. J. G. Love presented "Transplantation of the Spinal Cord for Paraplegia Due to Pott's Disease of the Spine."

* * *

Among the forty physicians from Minnesota who attended the first national meeting of the American Academy of General Practice were Dr. H. B. Clark, St. Cloud, and Everett J. Schmitz of Holdingford. They attended in the capacity of official state delegates. Noteworthy among business covered was the unanimously approved statement against compulsory health insurance. The group asked also that the American Medical Association standardize and regulate medical and surgical training programs as offered throughout the nation.

HARDRx LENSES
MAY BE SPECIFIED

Testing a HARDRx LENS

These controlled HEAT-TREATED prescription lenses are offered the patient where added protection and safety is desirable. Excellent for all children's glasses where added safety is desirable. A HARDRx Lens is ground to a minimum of 2 mm. thickness at thinnest point.

For hazardous industrial use, BEN-SAFE lenses may be specified.

A meeting sponsored by the Dakota County Republican Committee was held in the public clinic of the Hastings State Hospital in March. Lectures on mental health were presented by Dr. Ralph Rossen, superintendent, and two of his assistants, Drs. Bradley and Brown. The 100 guests listened also to Superintendent Farrell of the Red Wing Training School as he talked on a program for correlating mental studies with delinquency problems.

* * *

Dr. Harvey Knoche, a graduate of Worthington College and the University of Minnesota in 1945, is establishing offices in Morgan in association with Dr. William E. Johnson. Dr. Knoche interned in Buffalo, New York, after which he joined the United States Public Health Service at the Marine Hospital in Portland, Maine, later serving in Mayport, Florida. Dr. Knoche then transferred to Detroit, Michigan, where he was in charge of chest diseases and, later, out-patient work.

* * *

Three Rochester physicians attended the Annual Clinical Conference of the Chicago Medical Society which took place in that city early in March. Each physician presented a paper to the group: Dr. J. L. Emmett spoke on "The Surgical Treatment of the Urinary Retention." Dr. H. M. Weber spoke on "Diagnosis of Early Intestinal Cancer," later participating in a round-table discussion. Dr. H. W. Woltman addressed the group on "The Influence of Arteriosclerosis on the Central Nervous System."

* * *

Recently the Mayo Clinic opened a lounge for members emeritus of the Clinic staff, of which there are sixteen at the present time. The room, equipped to serve as a library, writing room and lounge for social relaxation, is located on the fifth floor of the Clinic building. Present emeritus physicians are: Drs. Samuel Amberg, W. M. Boothby, W. R. Braasch, J. L. Crenshaw, B. S. Gardner, H. Z. Griffin, Christopher Graham, B. E. Hempstead, W. S. Lemon, A. H. Logan, W. C. MacCarty, J. C. Masson, Albert Miller, E. C. Rosenow, F. L. Smith, and C. G. Sutherland.

* * *

Hennepin County Community Health Day, held on March 4, brought together representatives of more than 300 women's organizations. Speakers for the occasion were: Dr. Gaylord Anderson, head of the public health department of the University of Minnesota Medical School; Dr. Clare Gates, Minneapolis Health Department physician; Dr. Hermina Hartig, public school physician; and Dr. Charles Merkert, public health chairman of the Hennepin County Medical Society. Also speaking were several representatives of lay organizations.

* * *

Dr. Gaylord W. Anderson, director of the school of public health at the University of Minnesota, attended an inter-American conference of health and sanitation officers held in Quito, Ecuador, March 27-April 2.

As a member of the staff of consultants with the division of health and sanitation of the Institute of Inter-

American Affairs, Washington, D. C., Dr. Anderson met with twenty-five or thirty health and medical officers from fourteen American countries.

The staff conference discussed institute affairs and planned the division's future program. Visits were made to several field projects.

* * *

Giving the John Black Johnston Memorial Lecture at the University of Minnesota's Museum of Natural History in January was Dr. Paul C. Bucy, who is professor of neurology and neurological surgery at the University of Illinois Medical College in Chicago. The Johnston lecture is given each year in honor of Dr. J. B. Johnston who established the University's College of Science, Literature and Arts. Dr. Bucy's lecture was on the control of muscular infirmities by surgery of the brain. Dr. Bucy spoke also, on the following day, at the Center for Continuation Study, his topic being spinal injuries.

* * *

On Saturday, February 19, Dr. William A. Coventry, Duluth physician, was honored as the twenty-fifth person to be named to the local Hall of Fame.

Dr. Coventry, a graduate of the University of Minnesota, was one of the founders of the Duluth Clinic in 1916. He has served as president of the St. Louis County Medical Society, and he was governor of the American College of Surgeons in 1940. Dr. Conventry has also served as president of the Minnesota State Medical Association and is a recipient of an award from that group.

Dr. William D. Coventry of Duluth and Dr. Markham Coventry of Rochester are sons of Dr. Coventry.

* * *

The February issue of *Reader's Digest,* reprinting an article from the *American Mercury*: "You Add Years to Your Life," designated that the headquarters of the American Geriatrics Society was situated in Minneapolis. As a result of this mis-statement (headquarters are in Rhode Island), the office of the medical journal, *Geriatrics* (published in Minneapolis) has been plagued with hopeful inquiries by the aging who are looking for better health, greater strength and longer lives. The situation indicates great eagerness on the part of the increased population of the aged to use these later years to good advantage.

* * *
* * *

Reported as attending the course in pediatrics which was offered in February at the Center for Continuation Study by the University of Minnesota were the following: Dr. Ralph E. Wenzel, Blue Earth; Drs. Silas W. Giere, Richard P. Griffin, and Walter H. Sutherland, Benson; Dr. Troy G. Rollins, Elmore; Dr. Eugene L. Zorn, Erskine; Drs. Willard Hall Peterson and Lyle V. Berghs, Owatonna; Dr. Marie K. Bepko, Cloquet; Dr. Carl J. Luckemeyer, St. Cloud; Dr. Raymond C. Hottinger, Janesville; Dr. Harry Shragg, Elmore; Drs. Sidney Finkelstein and Philip A. Kleiger, Cass Lake; Dr.

Albert J. Lenarz, Brownersville. Physicians from Brainerd attending the course were Drs. Malcom D. McGreary and Francis J. Schnugg. From Willmar came Dr. Roger P. Michaels, and from Albert Lea, Dr. Robert A. Demo.

* * *

The 27,677 cases of poliomyelitis reported in 1948 makes the last year next to the worst in the twenty-two years during which the Public Health Service has been keeping accurate records for the country. In 1916, approximately 29,000 cases were reported. During January and February of this year, 759 cases have been reported —an all-time high for these two months. This compares with 270 cases for this two-month period last year, and 500 for the same period in 1947. Thus, the number of cases reported for January and February is not indicative of the year's total.

* * *

Dr. George E. Moore, a graduate of the University of Minnesota Medical School and specialist in surgery and onocology, was one of thirteen young physicians of the country to receive the John and Mary R. Markle Foundation Scholarship this year. This award, which totals $23,000, will cover a five-year period of study which Dr. Moore will take at the University of Minnesota. The Scholarship plan, begun in 1948, has made awards to twenty-nine physicians to date, and it is estimated by Mr. John Russell, executive director of the Foundation, that a total of fifty physicians will be recipients over the five-year period of the Foundation's existence.

BROWN & DAY INC. SAINT PAUL U.S.A. SERVICE QUALITY

and

Service

BROWN & DAY, INC.

St. Paul 1, Minnesota

The National Cancer Institute granted funds totaling $671,200 toward further laboratory and clinical research in cancer on March 25, it was announced by the Federal Security Administration. Three physicians from the University of Minnesota are being financed in their research in consequence. Dr. Jerome T. Syverton was granted $14,711 to continue his work in immunological studies on mice mammary cancer and leukemia. Dr. John J. Bittner, receiving $21,925, will study the genesis of mammary cancer in mice. A grant of $6,750 was made to Dr. Arthur Kirschbaum who is doing research on the induction of experimental therapy for leukemia in mice.

* * *

Dr. Myron J. Weaver, present assistant dean of the University of Minnesota Medical School, will leave the University in July to become dean of the new medical school at the University of British Columbia near Vancouver, Canada. The school will open in the fall of 1950.

Dr. Weaver has served on the faculty at the University of Minnesota for six years. He is an attending physician at the Minneapolis General Hospital, and senior attending physician at the University Hospitals.

An alumnus of Wheaton College and the University of Chicago, Dr. Weaver began his work at the University of Minnesota in the capacity of assistant professor of preventive medicine and public health. He was named to his present position in 1944.

* * *

Dr. Malcolm A. McCannel of St. Paul has recently become associated with Dr. Walter Camp, with offices in Minneapolis. Dr. McCannel's newly assumed practice is limited to opthalmology and opthalmic surgery.

A graduate of the University of Minnesota, Dr. McCannel received his M.D. degree from Temple University School of Medicine, Philadelphia, Pennsylvania, in 1941. He interned at St. John's Hospital in Brooklyn, New York, transferring later to Ancker Hospital in St. Paul. He obtained a teaching Fellowship in opthalmology at the University of Minnesota, doing graduate work at the New York Postgraduate Hospital in New York. In 1946, Dr. McCannel received a Master of Science degree in ophthalmology from the University of Minnesota and shortly thereafter was certified as a Diplomate of the American Board of Ophthalmology.

* * *

The "outstanding young man in Minneapolis for 1948" designated by the Junior Chamber of Commerce of Minneapolis is Dr. Robert A. Huseby, assistant professor of cancer biology at the University of Minnesota. The award was conferred on Thursday, March 10, at a "Bosses Night" dinner at Coffman Memorial Union.

In 1948, Dr. Huseby was awarded the William A. O'Brien assistant professorship in cancer, a field he has specialized in since 1941 when he first worked with Dr. M. B. Visscher, head of the department of physiology. For a year (1944) Dr. Huseby studied at the Rockefeller Institute in New York, under the scholarship award, the International Cancer Research Fellowship. His present

work is with Dr. John Bittner. Dr. Huseby is a native of Minneapolis and a graduate of the University of Minnesota Medical School.

* * *

Three Minnesota physicians have issued a report recently on the medical care afforded the Indian population. Drs. W. F. Braasch, Rochester; B. J. Branton, Willmar, and A. J. Chesley of St. Paul, have served as an investigation committee sponsored by the American Medical Association. The committee was established shortly after the dismissal of twenty-eight positive tuberculous Indian patients from an up-state sanatorium because of insufficient subsidy from the United States Government. Listing a seven-point program, the report asks for the construction of new hospitals for the Indian territories and for an educational program which will work towards the eventual integration of the Indian with contemporary American educational, health and social standards—a change which, the committee stated, would be economically and socially beneficial to the entire Northwest area.

* * *

The Saturday Evening Post, in two successive January issues, recognized the work of several Minnesota physicians. The first article, "Are We Winning the War Against TB?" told of the work of Drs. Corwin Hinshaw, F. M. Feldman and Karl Pfuetze and their work with streptomycin. Dr. Hinshaw is president of the American Trudeau Society and a member of the Mayo Clinic staff. Dr. Feldman is now living in Washington, D. C., and Dr. Pfuetze is medical director of the Mineral Springs Sanatorium at Cannon Falls.

The second of the two articles was concerned with Dr. John S. Lundy who is head of the Mayo Clinic section on anesthesia. Entitled, "Sing Me to Sleep, Doctor," the article told of Dr. Lundy's work, describing also an oxygen intake signal unit which has been developed by Drs. Albert Faulconer and Roger W. Ridley of the Mayo staff, with the aid of R. E. Jones of the Clinic's engineering department.

* * *

Bids on the construction of the new student health service building were opened by University of Minnesota officials during the first week of April.

The site of the new building will be the area just west of University Hospitals and south of the Botany building. The building will be four stories high and will face on Church Street with a frontage of 183 feet. It will be eighty-two feet in depth.

Contained in the building will be examination rooms, doctor's offices; a large eye, ear, nose and throat clinic; a dental clinic with space for ten dental chairs; an x-ray section and spacious waiting lounges. No bed space has been provided in plans for the new building as the health service will retain its bed space on the fourth and fifth floors of the present building, which is a part of the University Hospitals plant. A tunnel under Church Street will connect the two buildings.

Estimated cost of the building will be in excess of $750,000, and the structure will be paid for out of health service earnings. Magney, Tusler and Setter, Minneapolis architects, prepared the plans.

Just a word of THANKS

in appreciation of courtesies extended us in this and past meetings.

Yours for a successful convention—

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 S. Honore St., Chicago 12, Ill.

Indicative of the widespread interest shown by both medical and lay groups of Minnesota concerning the problems posed by compulsory health insurance and socialized medicine, are meetings devoted to lectures and discussion groups dealing with this problem. Among such meetings recently held are the following:

Dr. Donald K. Freedman, a staff member of the Arrowhead Health Center, Inc., spoke before the Saturday Lunch Club at a meeting held at the Medical Arts Building in Duluth late in February.

Dr. Martin O. Wallace spoke to the Arrowhead Civic club in Duluth late in January at a meeting held in the Arrowhead Hotel. He spoke also before a meeting of the Duluth Republican Women's Club on the same topic.

Dr. Myron Weaver, assistant dean of the University of Minnesota Medical School, speaking in February at the Center for Continuation Study during a course on hospital administration, expressed his view on the trends and problems concerned with socialized medical plans.

Dr. John W. Beuning, public relations officer of the Stearns-Benton Medical Society, spoke at the regular meeting of the East St. Cloud Boosters Club in February, discussing similar issues.

Dr. Haddon M. Carryer of Rochester spoke before the Mayo Foundation in February. Dr. Carryer, acting as secretary of the Olmsted-Houston-Fillmore-Dodge County Medical Society, spoke in explanation of the implications of the Oscar Ewing Report.

Dr. A. W. Adson of Rochester, past president of the Minnesota State Medical Association and member of the State Board of Medical Examiners, spoke before the Minnesota House of Representatives in March, expressing his views on the co-operative medical care bill.

The 1949 Farm Forum, which was held on March 10 and 11 at the Radisson Hotel in Minneapolis, under the sponsorship of the Chamber of Commerce, launched a debate on compulsory health insurance which is one of the issues confronting farmers at the present time.

Dr. Mitrofan Smorszczok of Freeport, a displaced Polish physician, lectured over station KFAM on March 11, presenting a report on socialized medicine as it has operated in various European countries. His talk, "Socialized Medicine as I Saw It," was given as one of a radio series on this problem being sponsored by the Stearns-Benton Medical Society. Earlier that same week, on March 9, Dr. Smorszczok spoke before the Exchange Lunch Club at the St. Cloud Hotel. His talk was descriptive of state subsidized medicine as found specifically in the USSR.

Speaking before the Saturday Lunch Club in Duluth on March 12 was Dr. Martin O. Wallace. Dr. Wallace explained his view of socialized medicine to the attending members, stating that he feared that the standard of medical service would be lowered with the advent of a government-sponsored medical plan.

Dr. H. J. Jeronimus, Duluth physician and surgeon, spoke to the members of the second district Minnesota Nurses Association at St. Mary's Hospital, Duluth, on March 14. He urged that the government consider the solving of more stressing problems—sanitation, housing, and so forth—before attempting to better the already high level of health service in America.

HOSPITAL NEWS

Dr. J. T. Loughlin of Grey Eagle was elected president of the St. Gabriel Hospital medical staff on February 15, succeeding Dr. G. M. A. Fortier of Little Falls. Dr. A. M. Watson of Royalton was elected vice president, and Dr. R. J. Stein, of Pierz, secretary. Named to the Executive Committee were: Drs. R. T. Healy of Pierz, S. W. Watson of Royalton, and G. M. A. Fortier of Little Falls. The meeting was held in St. Gabriel's Hospital in Little Falls.

* * *

Re-elected as Chief of Staff at St. Mary's Hospital in Minneapolis this year, was Dr. F. B. Mach. Dr. Mach has been a member of the hospital staff for over thirty years.

* * *

Newly elected as chief of staff of the Fairview Hospital is Dr. Arthur C. Skjold. Dr. Silas Anderson has assumed the post of vice chief of staff; Dr. Harry Mixer, that of secretary, and Dr. Stanley Stone, that of treasurer. Elected to the Executive Committee were Dr. Donald B. Frane, Dr. Harry B. Hall, Dr. Louis J. Roberts, and Dr. R. W. Kouchy.

Ancker Hospital has established extra facilities recently for the care of children's heart diseases. Under the leadership of Dr. Ivan D. Baranofsky, assistant professor of surgery at the University of Minnesota Medical School, arrangements are being made so that Ancker Hospital can assume some of the care, treatment and surgery in heart cases formerly carried solely by the University Hospitals. Dr. Baranofsky will perform the greater amount of surgery, and a new one-bed room has been provided on the floor near his office in Ancker Hospital so that the problem of postoperative observation will be lessened.

BLUE SHIELD NEWS

On December 31, 1948, Minnesota Medical Service Inc., or Blue Shield—as it is more commonly called—completed its first year of service to the people of Minnesota. Much progress was made in that year, so much in fact that the Minnesota Blue Shield received national recognition from Paul R. Hawley, M.D., Chief Executive Officer, Associated Medical Care Plans, which is the co-ordinating office of all Blue Shield plans.

This wonderful growth can best be explained in the few words published in the *Blue Cross Bulletin,* January-February, 1949, which quotes Mr. A. M. Calvin, Minnesota Blue Cross-Blue Shield Executive Director: "With living costs high as they are today, paying for medical care has become a very serious problem for the majority of people. They are enrolling in Blue Shield because they find this non-profit benefit plan the right answer to their medical care problems."

The success of the Blue Shield plan in Minnesota to date is due to the support, loyalty and assistance given by the doctors of Minnesota, the Board of Directors of Blue Shield, by Mr. F. Manley Brist—the attorney who has spent much time attending meetings both organizational, state, and national, by the employes of Blue Cross and Blue Shield, and to the general public which has accepted Blue Shield in the same spirit that it accepted Blue Cross fifteen years ago.

The year 1948 was a good one for Minnesota Blue Shield and Blue Cross. This was also true nationally. Minnesota enrolled 130,369 participant subscribers, of which 100,000 were made effective as of December 31, 1948; and an income of $328,007.77 was received. A total of $169,269.90 (51.5 per cent) was returned to the subscribers in the form of payments to doctors of medicine for services rendered Blue Shield patients; and $32,860.80 (10 per cent of the income) is in reserve for unreported cases. A total of 61.5 per cent of income was used for subscribers' care. Operating expenses for the year amounted to $45,531.03 (13.9 per cent of earned income).

During the year allowances were made on 2,449 surgical cases in the amount of $113,813.44; this comprises 67.2 per cent of the total services allowed. Medical service rendered to hospitalized patients only (1,831 cases) amounted to $43,516.16 (25.7 per cent). Obstetrical services totalled 185 cases, amounting to $9,241.00 (5.5 per cent). The remaining amount of $2,699.00 (1.6

per cent) was allowed for such ancillary services as x-rays, anesthesia, assisting and after-care.

The greatest number of surgical services were for surgery of the bones, joints, and tendons, these amounting to 400 cases; gynecology, 337 cases; surgery of the skin, 309 cases; tonsillectomies, 212 cases; appendectomies, 210 cases. The largest amounts allowed on any one category were: $20,805.26 for gynecology, $16,045.50 for appendectomies, and $14,866.11 on surgery of the bones, joints, and tendons.

Blue Cross also had an outstanding year, and at the end of 1948 893,662 participant subscribers were enrolled. A total of $7,111,649.00 was allowed toward hospital bills of Blue Cross patients, an increase of 42.3 per cent over 1947; thus, 87.5 per cent of the Blue Cross income was returned to the subscribers in benefits. 11.2 per cent was used for administrative expenses.

A brief look at the national picture will show that national Blue Shield enrollment has reached 10,000,000, with an excess of $65,000,000.00 being paid for benefits during the past year. Blue Cross nationally now covers nearly 32,000,000 subscribers and total benefits paid during 1948 were over $250,000,000.00.

During February, the Minnesota Blue Shield office mailed a supply of Home and Office Medical Service Report forms to all its participating doctors. Unfortunately, many of the forms have been returned as unclaimed or unlocated. The mailing list in the Blue Shield office is maintained from the addresses appearing in the annual State of Minnesota Directory of Licensed and Registered Physicians and Surgeons. However, since many changes can occur between publication dates of each new Directory, it is requested that the Blue Shield office be informed of any address changes of the Minnesota doctors of medicine. In this way Blue Shield service can be improved to the satisfaction of all concerned.

Announcing the Opening of the

Crystal Lake Rest Home

A new, modern and beautifully equipped rest home, situated in "park-like" setting overlooking Crystal Lake. A registered nurse and large competent staff are prepared to give our patients semi-professional care. A limited number of private, semi-private and ward beds are now available for the immediate placement of chronic, convalescent and elderly patients. Your inspection of the premises is invited. Inquiries from you and your patients will be courteously answered. JUniper 1938, 3805-15 West Broadway, Robbinsdale, Minnesota.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

AESCULAPIUS COMES TO THE COLONIES. The Story of the Early Days of Medicine in the Thirteen Original Colonies. Maurice Bear Gordon, M.D. 560 pages. Illus. Price $10.00, cloth. Ventnor, N. J.: Ventnor Publishers, Inc., 1949.

EVERYDAY PSYCHIATRY. Second Edition. John D. Campbell, M.D. Diplomate American Board of Neurology and Psychiatry; Psychiatrist to St. Joseph's Infirmary and Crawford W. Long Hospital, Atlanta, Georgia; Instructor in Psychiatry, Emory University Medical School; Captain M.C., U.S.N.R. 394 pages. Price $6.00, cloth. Philadelphia: J. B. Lippincott Co., 1949.

CORONARY ARTERY DISEASE. Ernest P. Boas, M.D. Associate Physician, Mount Sinai Hospital, New York City, and Norman F. Boas, M.D. 399 pages. Illus. Price $6.00, cloth. Chicago: Year Book Publishers, Inc., 1949.

DOCTORS OF INFAMY; THE STORY OF THE NAZI MEDICAL CRIMES. By Alexander Mitscherlich, M.D., Head of the German Medical Commission to Military Tribunal No. 1, Nurenberg and Fred Mielke. Trans. by Heinz Norden. 172 pages. Illus. $3.00. New York: Henry Schuman, 1949.

In this book of 172 pages is found a story of the medical crimes perpetrated in Nazi Germany. It gives documentary evidence of the medical atrocities performed by Nazi physicians under the guise of necessary experimentation. It illustrates the depths of degradation which was reached by many of the German physicians who were believers and followers of a false ideology.

This book, although depressing, is well worth reading for the lesson it teaches of a medical professon that succumbed to Fascism.

JOHN F. BRIGGS, M.D.

LECTURES TO THE LAITY. 174 pages, price $2.50. New York: Columbia University Press, 1949.

This latest volume of the New York Academy of Medicine's Lectures to the Laity reflects a forward-looking perspective that does credit to the Academy. Six eminent authorities discuss research and progress upon six of the most vitally important frontiers of medical research.

The list of contributing authors begins with Lewis L. Strauss of the U. S. Atomic Energy Commission and the Naval Research Advisory Board, who discusses the atom in civil life. Sir Raphael Cilento, director of the Social Division of the United Nations, surveys the relationship between food and civilization. Dr. Edward J. Stieglitz covers the lively subject of geriatrics; Dr. Cornelius P. Rhoads looks into the future of cancer research; Dr. William C. Menninger covers the subject of psychiatry for everyday needs; and James B. Conant,

AR-EX COSMETICS, INC., 1036 W. VAN BUREN ST., CHICAGO 7, ILL.

President of Harvard University, contributes the final chapter, an acute and masterly discussion of the interrelation of pure and applied science in the field of medicine.

PATHOLOGY AND SURGERY OF THYROID DISEASE. By Joseph L. DeCourcy, M.D., Senior surgeon of the Good Samaritan Hospital, Cincinnati, Ohio, and Dr. Cornelius B. DeCourcy, resident member of staff of the Good Samaritan Hospital, Cincinnati, Ohio. 476 pages. Springfield, Illinois: Charles C. Thomas, 1949.

This book is a new and comprehensive discussion of every phase of thyroid anatomy, histology, pathology, pharmacotherapy and surgery, representing a review of more than 15,000 case histories of patients treated for thyroid disease at the DeCourcy Clinic, Cincinnati.

Dr. Joseph L. DeCourcy, author of the volume, is nationally known for his research in thyroid surgery. He has been a member of the American Goiter Association for two decades and a fellow of the American College of Surgeons. His son, Dr. Cornelius B. DeCourcy, is co-author of the work.

In addition to providing detailed information on new chemotherapy and the use of radio-active iodine in diagnosis and treatment, the book presents the most recent developments in thyroid surgery. The technique which has been perfected by the authors themselves is described in careful detail, supplemented by illustrations on each phase of the various procedures used. Meanwhile the authors have remained scrupulously unbiased in evaluating divergent or conflicting theories and principles, utilizing more than 673 references.

The book is a comprehensive and detailed review of the literature on every aspect of the many problems of the thyroid and the future of thyroid surgery.

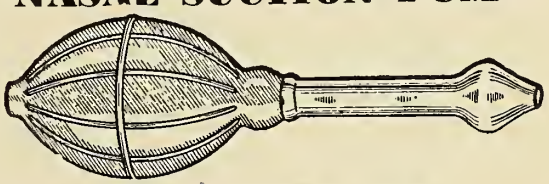
SAFEGUARDING MOTHERHOOD. By Sol T. DeLee, M.D., Clinical Instructor of Obstetrics and Gynecology, University of Illinois; Attending Obstetrician at the Chicago Maternity Center; Former Associate in Obstetrics and Gynecology, Cook County Hospital. 135 pages, Illus. Price $2.00. Philadelphia: J. B. Lippincott Co., 1949.

Motherhood, a sacred event for a woman that is more or less dreaded by all expectant mothers, is very beautifully covered in this treatise.

It is almost superfluous to make any gestures when none other than J. P. Greenhill, M.D., precedes the text of the book by an excellent foreword. He is the same gentleman who does such a splendid job in editing the Yearbook of Obstetrics and Gynecology.

It is safe to say that this book will reach 90 per cent of the laity mothers. It is clear; it is simple, and it is not arbitrary. I can see in it the same clearness and simplicity that is evident in my 3rd edition of Principles and Practice of Obstetrics by the late Joseph B. DeLee, M.D., who is an uncle of this author. With due respect to other books on obstetrics, I still treasure as a keepsake this 3rd edition for the reasons mentioned and because it brings back memories of my undergraduate days.

Safeguarding Motherhood tells the mother everything she needs to know and yet does not keep her away from her obstetrician.



I can safely recommend this book to any expectant mother.

JOSEPH F. BICEK, M.D.

GIFFORD'S TEXTBOOK OF OPHTHALMOLOGY. By Francis H. Adler, M.D., Professor of Ophthalmology, University of Pennsylvania Medical School. 4th edition. 512 pages. Price $5.50. Philadelphia and London: W. B. Saunders Company, 1947.

This comprehensive revision was completed by the ophthalmologist chosen for this task by Dr. Gifford. Dr. Adler strove to carry out the original purpose of

379 Robert St. St. Paul

the textbook; that is, to cover facts of value to the medical student and general practitioner. To this end, he has given special attention to minimizing the more technical aspects (refraction and operative procedures) and enlarging on the practical fundamentals.

The revisor's interest in physiology resulted in a great increase in physological material in order that the principles underlying disorders of the eye may be understood more clearly. The chapter on "Disturbances of Ocular Motility" has been entirely rewritten. The chapters on "Ocular Manifestations of General Disease" and on "Ocular Disorders of the Central Nervous System" are expanded, pertinent and valuable. In the former, Dr. Adler considers more than sixty common diseases, their eye signs and symptoms, and treatment in each case. The chapter on therapeutic agents includes such new drugs as penicillin and streptomycin.

An innovation is the addition of bibliographic references at the end of each chapter. These are of most value to the graduate student. More than seventy per cent of the 431 excellent illustrations are new for this edition.

This textbook ostensibly may be written for medical students and general practitioners, yet its well-prepared, up-to-date material will be found very useful to the postgraduate student or practicing ophthalmologist.

F. F. Wipperman, M.D.

Florence Nightingale Saw the Light

SHE gave us the light to see the need for a major service in each community. If today you were to take our nursing service from us it would cause a great catastrophe. Nursing is a new profession.

Florence Nightingale started the first nurses' training school less than 100 years ago. Thanks to her for light, vision and inspiration.

Glenwood Hills also saw a light of similar quality 10 years ago when it felt this urgent need for properly trained *psychiatric nurses* to "serve the community, aid the doctor and care for the patient."

Competent, qualified trained nurses are taught by *"competent, qualified* and *trained instructors."*

You doctors can greatly help recruit students by selecting them in your community. Our best graduates come doctor-recommended.

Tuition is free. There is a small charge for matriculation. Help eliminate the nursing shortage by choosing a promising girl, 17 or over, in your community, and sending us her name.

This baby's mother learned about Mead's Oleum Percomorphum from her physician, not from public advertising or displays.
"Servamus Fidem"
HOW much sun does the infant really get?
Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Mead's Oleum Percomorphum is a prophylactic against rickets available 365¼ days in the year, in measurable potency and in controllable dosage. Use the sun, too.
Mead Johnson & Co., Evansville, Ind., U.S.A.

Contact of a sensitized body cell with an allergen and subsequent release of histamine is considered to be the mechanism of allergic disorders.

Blocking the action of histamine, BENADRYL prevents reaction in cells that have been sensitized. Relief of symptoms is gratifyingly rapid, usually occurring within an hour or two after the first dose. And treatment with BENADRYL is simple, convenient, and inexpensive.

BENADRYL®

BENADRYL has been found highly effective in a wide variety of allergic states, ranging from seasonal, such as hay fever, to the non-seasonal, such as acute and chronic urticaria, angioneurotic edema, vasomotor rhinitis, contact dermatitis, erythema multiforme, pruritic dermatoses, dermographism, serum sickness, food allergy, and sensitization to drugs, such as penicillin and the sulfonamides.

BENADRYL hydrochloride (diphenhydramine hydrochloride, Parke-Davis) is available in a variety of forms to facilitate individualized dosage and flexibility of administration, including Kapseals®, Capsules and a palatable Elixir.

The usual dosage of BENADRYL is 25 to 50 mg. repeated as required. Children up to 12 years of age may be given 1 to 2 teaspoonsful of Elixir Benadryl.

the difference is noteworthy

Trimeton

(brand of prophenpyridamine)

TRIMETON* differs from most other antihistaminic agents in not being a derivative of ethanolamine or ethylenediamine. This difference is noteworthy and is responsible for the gratifying clinical results obtained. In one study of 227 patients with various allergic conditions[1]

83% obtained benefit from Trimeton

Side effects, common to all antihistaminics, occur with TRIMETON, but only a few patients find that they cannot tolerate the drug.[1]

Relief from allergic symptoms is usually obtained with one TRIMETON 25 mg. tablet three times daily; in some patients half this dosage is sufficient. The action of TRIMETON lasts from four to six hours.[2]

PACKAGING: TRIMETON (1-phenyl-1-(2-pyridyl)-3-dimethylaminopropane) is available in 25 mg. tablets, scored, in bottles of 100 and 1000.

Modern ELECTRO-CARDIOGRAPHY

Direct-Recording Cardiotron

Portable, rugged, electricolly operated without batteries. Cordiotron is available with or without stand.

The first successful *Direct-Recording* Electrocardiograph...

With more than 1200 now in use throughout the world, the Cardiotron has established the principle of instantaneous recording in general clinical electro-cardiography.

The Cardiotron is fast, accurate and sensitive. It makes an *immediate* black and white cardiogram—on *permanent* chart paper. It is free from skin resistance errors. It reveals more information than any other electrocardiograph instrument.

IMPORTANT: Factory-supervised installation and service are available in most parts of the world. Good deliveries are scheduled. Cardiotron is sensibly priced.

Send for 12-page descriptive booklet

when Milk becomes a dietary dilemma

Problem: When casein or other animal protein sensitivity renders all natural or processed milks* contraindicated in the pediatric dietary, because of eczematous, gastro-intestinal or other reactions, how can allergy be avoided and proper infant nutrition still be maintained?

Solution: Replace milk with Mull-Soy, the liquid hypoallergenic soy food—completely free of offending animal proteins. Mull-Soy is a biologically complete vegetable source of all essential amino acids, and closely approximates whole cow's milk in fat, protein, carbohydrate, and mineral content when diluted 1:1 with water. It is quickly prepared, palatable, easily digested and well-tolerated—equally desirable for infants, children or adults.

**Goat's milk and processed cows' milk have unmodified casein factors.*

routine for discovery

The national total of undiagnosed or "unknown" diabetics may run from a million to two or even three.[1,2] Modern treatment, when promptly initiated, can do much to prevent metabolic decompensation and to minimize diabetic complications. Therefore, the clinical revealment of diabetes mellitus at an early stage is essential.

Thus, "all patients who present themselves to the physician for an examination should have a routine urine examination."[3] In this phase of practice, the advantages of *Clinitest*® tablets for urine-sugar analysis are considerable.

Clinitest is dependably accurate, yet it takes only a few seconds to perform. The test is simple—no external heat need be applied; interpretation is by direct color comparison. *Clinitest* is convenient both for the doctor's office routine and for the diabetic patient's prescribed sugar-level checkups.

Announcement

NATIONAL POSTURE WEEK

will be observed this year

OCTOBER 17—22

We make this announcement so early in the year because many hundreds of physicians, surgeons, industrial physicians, health officers and other members of the profession have over the last ten years scheduled the event for May.

The change to October has been made in deference to requests from schools, colleges, adult education groups and community welfare organizations like the "Y's." They now look forward to wider and more effective participation because they can key the event into their health education and physical fitness programs early in the school term, thus avoiding vacation season interruptions.

As National Posture Week enters upon its second decade, it is our privilege to thank the many, many physicians who have given it their approval as a worthy contribution to public health education. We pledge ourselves to carry on in the future as we have in the last ten years with National Posture Week and the daily work of The Samuel Higby Camp Institute for Better Posture. We shall do this to the limit of our resources in accordance with the ethical precepts of the profession.

MEAT...
and Physical Rehabilitation

Any marked loss of weight in the nonobese patient deprives the organism of a considerable amount of protein, apt to lead to severe protein deficiency. A weight loss of 5 Kg. does not appear large as such. Yet it is estimated that it may well entail a simultaneous loss of as much as 900 Gm.—or two pounds—of tissue protein,* taken from the scant protein stores of the body, from the muscles, liver and other viscera. Prevention of such large protein losses or rapid replacement of depleted protein stores is imperative. Nitrogen balance must be re-established as quickly as possible to promote local healing and general recovery in many surgical conditions, in severe burns, in metabolic disturbances, and following overwhelming infections.

Meat as the primary source of protein affords a number of special advantages in the period of actual dietotherapy as well as during recovery and rehabilitation. It is of excellent digestibility so that it can be easily eaten two or three times a day to satisfy increased protein requirements.

The appetizing taste appeal encourages simultaneous intake of other valuable foods, especially desirable in the presence of anorexia.

All meat is notably rich in biologically complete protein, from 17 to 20 per cent of its uncooked and from 25 to 30 per cent of its cooked weight. Furthermore, meat ranks with the best sources of B-complex vitamins and iron, important nutrient factors in physical rehabilitation.

The ever-moving frontier

Research on vitamin knowledge in the field of nutrition has come a long way since the early published researches of McCollum, Mendel and Funk. The science of nutrition is no longer the stepchild of medicine, nor the poor relation of agriculture. In particular, our understanding of the need for vitamins in human nutrition has enormously increased. Vitamins constitute in the aggregate the *sine qua non* for cellular respiration, reproduction, growth and repair.

For the past 25 years, biochemists have pressed forward a continually moving frontier of scientific discovery in the field of nutrition. In recent years, *Lederle* has been in the vanguard of this movement, its investigators being well known for their achievements with folic acid, pyridoxine, biotin, the pantothenates, liver extract, and allied substances. There will be no slackening in the efforts of this organization to uncover additional aids to better health and better living.

LEDERLE LABORATORIES DIVISION AMERICAN Cyanamid COMPANY
30 ROCKEFELLER PLAZA • NEW YORK 20, N. Y.

WHY A FIBRIN HYDROLYSATE ?

AMINOSOL 5% with Dextrose 5% was developed as a protein hydrolysate after much research work on different source materials. Numerous nutrition experiments pointed to the unique role of fibrinogen as a normal constituent of the body. A recent clinical investigation[1] indicates that peptides in a protein hydrolysate derived from fibrin as a source material are retained better and are excreted to a considerably smaller extent than are the peptides derived from other protein source materials.

Fibrin was selected as the source for AMINOSOL because of its completeness as a food protein. The result is a hydrolysate which, after stringent animal and human use, has been shown to have high biological value and stability. AMINOSOL is assayed for the absence of anaphylactic properties by a very rigid procedure. Freedom from pyrogens is assured. The practical absence of sodium ion recommends it for use in cardiac and renal conditions where a salt-free diet is indicated.

AMINOSOL is supplied in 500-cc. and 1000-cc. Abbott Intravenous Solution Containers, ready to use. Obtain added safety and convenience in administration by using the sterile, disposable VENOPAK* equipment.

PROPOSALS FOR THE EXTENSION OF MEDICAL CARE

HADDON M. CARRYER, M.D.
Rochester, Minnesota

THIS is indeed a tempestuous time in American medical history. There is an increasing tendency in governmental philosophy toward a series of platforms constructed under the various sociologic, educational and medical services which the government has sponsored. We must study the means by which such benefits are to be provided. We must evaluate their effect upon individual liberties with a careful consideration as to whether obvious advantages are outweighed by a deterioration of services and find whether an undue burden is placed upon those at whose expense such services are to be provided. The gradual transition which has been going on toward a solution of many glaring faults in medical service, as it is now provided, has been snowballed into an urgent problem by the unexpected Democratic victory last year.

Most of us physicians are so overwhelmed by the more pressing needs of "keeping up" in our knowledge and practice of the scientific aspects of medicine that we scarcely have an opportunity to review its sociologic aspects. It was because of this lack of information on the part of the average physician and his dilemma at the widely divergent views being forced upon him that this program was arranged.

As a necessary prerequisite to an evaluation of whether we do, or do not, need any radical change in the manner in which medicine is practiced in this country, one must first evaluate the status of our nation's health. There are widely divergent opinions with respect to this problem.

On one side of the question we have the findings of Oscar R. Ewing, the Federal Security Administrator, who has stated that "during the last generation, the United States steadily improved its health record, but the Nation, and the people, still suffer severe losses through sickness, disability, and death, much of which is unnecessary. Every year, 325,000 people die whom we have the knowledge and the skill to save. Every year, the Nation loses 4,300,000 man-years of work through bad health. Every year, the Nation loses $27,000,000,000 in national wealth through sickness, and partial and total disability. The record of Selective Service examinations during the war is widely known—5,000,000 men declared unfit physically or mentally for the armed services of their country." It is primarily on these conclusions that Mr. Ewing bases his opinion that there needs to be a thorough change in the manner in which medicine is practiced in this country.

On the other side of the question we have a report made by the Brookings Institution, a non-medical organization. This report was requested in May, 1947, by Senator H. Alexander Smith, of New Jersey. In February, 1948, the report was ready for publication.

The Brookings Institution's conclusions, in brief, are these:

1. Probably no great nation in the world has among its white population better health than prevails in the United States.

2. It is apparent that the United States under its voluntary system of medical care has made greater progress in the application of medical and sanitary science than any other country.

Dr. Carryer is secretary of the Olmsted-Houston-Fillmore-Dodge County Medical Society.

3. The non-whites in the United States have materially poorer health than the whites, but the evidence does not indicate that this condition is primarily or even mainly due to inadequacy of medical care.

4. The advances in health among both the whites and non-whites that have been made in the United States in the past four decades do not suggest basic defects in the American system.

5. Although the so-called draft statistics have been widely used to show bad health among American people, they are unreliable as a measure of the health of the nation.

6. Present medical care in the United States compares favorably with that which existed in other leading nations prior to the second World War.

7. The conditions in extremely poor rural areas cannot be solved by subsidies only

8. The United States has some individuals and families not possessed of the resources to enable them to pay for adequate medical care. In the future, as in the past, provision must be made for them through public funds or philanthropy.

9. Compulsory health insurance would necessitate a high degree of governmental regulation and control over the personnel and the agencies engaged in providing medical care.

10. The problem of eliminating politics from government administration is extremely difficult. It does not seem probable that politics could be eliminated from medical care supplied under a governmental system.

11. Compulsory insurance would inject the government into the relationship between practitioner and patient.

12. The administration of compulsory insurance would require thousands of government employes for accounting, auditing, inspection and investigation.

13. The cost of medical care presumably would increase because of administrative expenses, the tendency of insured persons to make unnecessary and often unreasonable demands upon the medical care services and the tendency of some practitioners and agencies to take advantage of the system for their own financial advantage.

14. The adoption of compulsory insurance would not immediately make available adequate service for all, because there are not at present the facilities nor a sufficient number of trained and experienced physicians, dentists and nurses to meet the demand which would result from compulsory insurance.

15. It seems questionable whether a country which once embarks on compulsory insurance can turn back. If such a program is once inaugurated, attempts must be made to remedy defects by more complete government control and administration.

It was the opinion of the Brookings Institution that most consumer units have the capacity to pay for medical care by voluntary prepayment medical care insurance if they would give it a high priority with preference over expenditures for automobiles, alcoholic liquors, tobacco, recreation and savings.

The widespread use of draft statistics as a means of portraying a deplorable situation in the health of man in this country has been widely criticized by Dr. Maurice Friedman, formerly of the University of Pennsylvania Medical School. He has pointed out that nearly two-thirds of the rejections were because of health conditions beyond the power of the medical profession to prevent or correct, regardless of the amount of medical service available and regardless of the cost of medical care. Only 20 per cent of the total rejections could have been influenced by medical care.

Because of the controversial nature of the Ewing report I should like to return once more to the details contained in it. In Ewing's conclusions regarding key health problems, he first stated that medical man power is insufficient and poorly distributed. In his opinion we have only 80 per cent as many physicians as we need and even greater shortages of other medical personnel; however, we do not have enough medical colleges, training schools and teaching hospitals to close the gaps between need and supply at any time in the foreseeable future. Secondly, our hospitals and other such facilities have not kept pace with our needs; we have only 50 per cent as many acceptable hospital beds as we require. Third, the Nation's health resources are not used to full efficiency; public and private services alike have for the most part grown up without effective planning. Fourth, our search for new knowledge about man and his human needs is feeble compared with our search for knowledge that will contribute to material wealth. According to Ewing, little more than 10 per cent of the more than $1,000,000,000 spent annually for research goes for medical and related sciences. Fifth, perhaps the basic lack of our entire health effort is the absence of any method which would permit the individual, regardless of his level of personal income, to obtain the kind of services he needs to achieve better health. Ewing stated that a scant 20 per cent of our people are able to afford all the medical care they need.

With these considerations in mind, Ewing has outlined a program which he sponsors. First, regarding medical manpower, he advocated increasing sharply our total production of manpower through training programs and financial and other

support, to expand medical colleges and to establish new ones until by 1960 our annual production of medical power in all categories has been increased by 40 to 50 per cent. This by 1960 should produce 227,000 active physicians (the present supply being 190,000), 95,000 dentists, (we have 75,000 now), 443,000 nurses (at present we have 318,000), and other supporting personnel by comparable amounts.

Second, regarding hospitals, Ewing recommended doubling the number of acceptable hospital beds as rapidly as possible, certainly within fifteen years, and at the least by 1960 adding 600,000 beds to our hospitals, and building such additional health centers and auxiliary facilities as surveys have shown to be necessary throughout our country.

Third, regarding local organization, "The states and communities themselves ultimately will set their own multiple goals for carrying out their parts of the program for better health." In Ewing's opinion we should attempt to provide federal assistance in establishing and maintaining adequate medical health units everywhere and in increasing and improving the training of public health workers to the end that their number shall be doubled.

Fourth, regarding individual costs, Ewing recommended that we should "provide that all people shall have access to such health and medical services as they require through a system of insurance covering the entire population." Because of the inability of millions of people to meet the costs of health services, Ewing stated that he is compelled to urge as strongly as possible that Congress enact, as President Truman has recommended, a system of government prepayment health insurance in the terms in which it has been mapped out. He pointed out that no agreement was reached at the National Health Assembly with respect to the national health insurance plan and that hence his recommendation is not based upon the action of the assembly.*

Fifth, regarding research, Ewing stated that we should increase our investment in medical and related research as rapidly as scientists can be trained, until the total national research is adequate to keep pace with our expanding needs. By 1960, federal nonmilitary research expenditure should reach a total of $80,000,000 to $100,000,000 annually if enough qualified scientists are available.

Sixth, Mr. Ewing pointed out the goals for certain special programs to focus attention on mental health as a leading area for medical progress in the last half of this century; to enable everyone in the nation to enjoy a happy, active, productive maturity by controlling chronic diseases and by relieving other physical and mental problems of adult life; to provide rehabilitation services for the 250,000 men and women who become disabled through illness or injury every year and to insure that every child in the country has the utmost degree of health. Accident prevention and sanitation ought to be stressed. The drive against venereal disease and tuberculosis should be pushed. The knowledge of nutrition should be broadened.

Ewing has estimated the government expenditures for his civilian health program in the year 1960 when such a program will have been completely active. He estimated the cost to be about $4,000,000,000. Ewing suggested that the money which will be expended in his health program will be derived from a 3 per cent and eventually 4 per cent annual earning tax on salaries up to $4,800 a year, probably to be divided between the subscriber and the employer.

The federal government may use general revenue to supplement the contributions as necessary in the amounts equivalent to a fixed maximal percentage of contributions.

Critics of the Ewing program have indicated a number of inadequacies, inconsistencies and statistical errors in his analysis. It has been pointed out that the National Health Assembly, which was called to consider the nation's health and the opinions of which Mr. Ewing's program is supposed to represent, was a "loaded" assembly. Many of those physicians who were members of it were selected from a small group which favors compulsory health insurance. It has been pointed out that only three months elapsed between the time the report was authorized and the time it was presented to the President. It is obvious therefore that the report had been largely prepared by Ewing before the National Health Assembly gathered to consider the problem at hand. The report has been widely criticized because of its statement that 325,000 persons per year die unnecessarily. This figure includes 150,000 deaths attributable to cancer or to heart disease and

*The medical care section of the National Health Assembly recommended voluntary prepayment group health plans as being the best available means at the time of bringing about improved distribution of medical care, particularly in rural areas.

40,000 deaths attributable to accidents. It is unlikely that medical care would have materially affected these conditions. Other figures have been derived from tuberculosis death rates, noting differences between states but without proper evaluation of factors other than medical care which may have contributed to the differences.

It would take approximately 1,000,000 nonprofessional employes to develop the system which has been suggested by Mr. Ewing. There would be a three-year tuning-up period of vast expenditure without any medical service being provided. It has been pointed out that Mr. Ewing's estimates of the cost ($4,000,000,000) are far less than the actual amount will probably represent. Estimates as high as $10,000,000,000 to $14,000,000,000 yearly are considered by some to be closer to the actual cost.

Dr. Walter Judd, Congressman from Minnesota, recently called attention to the probable costs of socialized medicine if it is introduced. He cited experience in other countries where the program has been tried and where it has cost approximately $240 per person each year. He pointed out that an individual could receive the same benefits through private medical care and hospital insurance programs for approximately $60 annually.

Critics of Mr. Ewing's plan have pointed out that the medical histories of a physician may be examined, thereby destroying a certain phase of the patient-physician relationship. His criticism of the adequacy of medical care has been attacked. While the wealthy had 20 per cent more house calls and office visits than the poor, there is no difference in hospital services given to the wealthy and the poor.

Ewing has stated that only 7,000,000 people in the United States live in communities meeting minimal standards set up for public health services. If New York City (population more than 7,000,000) has adequate public health measures, the rest of the country is in bad shape.

While draft statistics have been proved to be of little value, Ewing and his co-workers persist in using them to sell their plan.

It would be amiss in a discussion of this sort if we were not to consider S-5, the new version of the Wagner-Murray-Dingell Bill. In each session of Congress for the past decade these men have introduced some measure to provide for compulsory health insurance. Each of the series of bills provides that compulsory health insurance shall be administered by a national health insurance board of five men, one of whom shall be a doctor of medicine. The Surgeon General of the Public Health Service and the Commissioner for Social Security are members ex officio. The act reads that "All functions of the Board shall be administered by the Board under the direction and supervision of the Federal Security Administrator." There is likewise to be a medical advisory council of sixteen members appointed by the Federal Security Administrator, six members of which shall be selected from the various medical professions. The benefits of the Wagner-Murray-Dingell Bill provide that all self-employed people and practically all wage and salary earners, including federal government employes, are eligible for benefits consisting of medical services, dental services, home nursing services, hospital services and auxiliary services. The bill provides that payment to physicians, dentists, nurses, technicians and hospitals will be through designated local agencies with funds collected by the federal government and allocated by the National Health Insurance Board. No provisions are made in the bill for the necessary tax to provide the funds. The bill was submitted on the assumption that a special tax measure would be introduced in the House of Representatives embodying payroll tax deductions and methods of payment by the self-employed. In this manner an annual fund would be collected to be administered and dispensed by the board under the direction and supervision of the Federal Security Administrator. In this bill provisions are made for expanding public health services and federal subsidy for hospital construction.

Throughout the country there has been a great deal of criticism directed against the provisions as outlined in the Wagner-Murray-Dingell Bill. It has been pointed out that countries do not socialize medicine in a vacuum but work for the socialization of the entire economy, as they are doing in Great Britain. High-sounding purposes stated in the preamble are widely publicized rather than the means of effecting them, and it is generally conceded by students of the problem that the bill as it has been introduced will not carry out the objectives as stated in the preamble. As the bill is written, every physician after the enactment of the law will be held responsible, not solely to his patient as he is at present, but jointly to the state

and to the patient, the state presumably having precedence over the patient in this regard. Under the provisions of the Wagner-Murray-Dingell Bill, a patient normally may consult a specialist only with the permission of the government insurance physician. Of course, if he could not get permission of his physician, he could appeal to the government referee or as he is called "the administrative medical officer." That is the government official to whom the patients and physicians would be referred if they were dissatisfied with anything. Such officers would be charged with the responsibility for policing the health insurance system. Under the Wagner-Murray-Dingell Bill, there would be no recourse within the benefit of the bill for a patient when the government physician would say, "You may not go to a specialist." The cost of administering the bill would be prohibitive.

Another stated objective of the Wagner-Murray-Dingell Bill is the patient's freedom of choice of physicians. There would be only a partial freedom, however, under a capitation system. The representatives of the two leading nongovernmental lobbies sponsoring compulsory health insurance, Michael M. Davis, of the Committee for the Nation's Health, and Ernst P. Boas, of the Physicians Forum, have both conceded that the "fee for service" basis of payments will have to be abandoned and the capitation system used under national compulsory sickness insurance. There are a number of deficiencies in the capitation system. One is that patients who fail to choose a physician have to be assigned, since the physician's income is dependent on the number of patients on his list. What is to be done if a certain number of patients say that they are not going to get on any physician's list? The Wagner-Murray-Dingell Bill says that after a certain period, people would be notified that they would be assigned, and they would be assigned to the list of some physician. Under the capitation system, patients are worth so much per head per year to the physician on whose list they appear.

In the Wagner-Murray-Dingell Bill power would be centralized solely in Washington and solely in the hands of the Federal Security Administrator.

Other legislation which has been considered by Congress is more constructive. The Hill-Burton hospital bill which became law in 1946 provides an appropriation of $3,000,000 for state-conducted surveys of need and $75,000,000 annually for a five-year period for the construction of hospitals and related facilities. Before any single project is approved, sufficient evidence must accompany the request to show that two-thirds of the total cost of construction is available from other than federal sources and that financial support is adequate for the maintenance and operation of the hospital or related facility after completion. Three months ago 540 applications had been approved. The American Medical Association has strongly supported the Hill-Burton hospital bill.

Although the American Medical Association has come in for a great deal of criticism in recent years and has been accused of failing to comprehend the sociologic changes which are taking place in our country, it is evident from its program, a résumé of which follows, that this criticism is not justified.†

PROGRAM OF THE AMERICAN MEDICAL ASSOCIATION FOR THE ADVANCEMENT OF MEDICINE AND PUBLIC HEALTH

A Federal Department of Health

1. Creation of a Federal Department of Health of Cabinet status with a Secretary who is a Doctor of Medicine, and the co-ordination and integration of all Federal health activities under this Department, except for the military activities of the medical services of the armed forces.

Medical Research

2. Promotion of medical research through a National Science Foundation with grants to private institutions which have facilities and personnel sufficient to carry on qualified research.

Voluntary Insurance

3. Further development and wider coverage by voluntary hospital and medical care plans to meet the costs of illness, with extension as rapidly as possible into rural areas. Aid through the states to the indigent and medically indigent by the utilization of voluntary hospital and medical care plans with local administration and local determination of needs.

Medical Care Authority with Consumer Representation

4. Establishment in each state of a medical care authority to receive and administer funds with proper representation of medical and consumer interest.

New Facilities

5. Encouragement of prompt development of diagnostic facilities, health centers and hospital services, locally originated, for rural and other areas in which the need can be shown and with local administration and

†This recently announced program is an extension of the program sponsored by the American Medical Association over the past two decades.

control as provided by the National Hospital Survey and Construction Act or by suitable private agencies.

Public Health

6. Establishment of local public health units and services and incorporation in health centers and local public health units of such services as communicable disease control, vital statistics, environmental sanitation, control of venereal diseases, maternal and child hygiene and public health laboratory services. Remuneration of health officials commensurate with their responsibility.

Mental Hygiene

7. The development of a program of mental hygiene with aid to mental hygiene clinics in suitable areas.

Health Education

8. Health education programs administered through suitable state and local health and medical agencies to inform the people of the available facilities and of their own responsibilities in health care.

Chronic Diseases and the Aged

9. Provision of facilities for care and rehabilitation of the aged and those with chronic disease and various other groups not covered by existing proposals.

Veterans' Medical Care

10. Integration of veterans' medical care and hospital facilities with other medical care and hospital programs and with the maintenance of high standards of medical care, including care of the veteran in his own community by a physician of his own choice.

Industrial Medicine

11. Greater emphasis on the program of industrial medicine, with increased safeguards against industrial hazards and prevention of accidents occurring on the highway, home and on the farm.

Medical Education and Personnel

12. Adequate support with funds free from political control, domination and regulation of the medical, dental and nursing schools and other institutions necessary for the training of specialized personnel required in the provision and distribution of medical care.

The American Medical Association considers it unfair to include in any draft legislation which may be enacted, clauses which would specifically affect physicians. It is attempting to provide for the armed forces those medical officers which they will require. Recently it sent letters to 7,600 physicians under the age of twenty-six years, to which they had received 750 replies. Four hundred fifty physicians asked for a commission in one of the armed forces.

A certain amount of opposition to compulsory health insurance has come about through the efforts of physicians. However, many nonmedical organizations have voiced opposition to such a plan.

In October, 1948, the American Legion adopted a resolution in which it was stated that that organization is "unalterably opposed to all efforts and movements to enforce socialized medicine upon the American people."

Recently the Farm Bureau Federation, a group including 1,325,000 families and the largest organization of its type in the country, telegraphed the Senate Labor and Public Welfare Committee an urgent appeal to defer action on compulsory health insurance.

Many labor leaders have been vociferous in their support of a program of compulsory health insurance. However, there is no record that the rank and file of union members have ever voted on the subject; in fact, there is no reason to believe that the average worker, if he has heard of the proposed health program, has more than the haziest idea of its provisions or its costs. Likewise lined up against the passage of a compulsory health insurance law, one may find the dentists, the insurance companies and probably the bulk of businessmen dependent upon free enterprise.

There is consternation among those who are defending the present system of medicine in America, regarding attempts on the parts of federal employes to influence legislation and the use of federal appropriations for this purpose. Such expenditures are illegal. However, on November 19, 1945, the Surgeon General of the United States Public Health Service sent a directive to others in his organization in which he stated: "The appropriate executive agencies of the government have been specifically instructed by the President to assist in carrying out this legislative program [referring to the health program] as presented to Congress on September 6, 1945." He continued: "Every officer of the public health service will wish to familiarize himself with the President's message and will be guided by its provisions when making any public statement likely to be interpreted as representing the official views of the Public Health Service."

Representative Forrest A. Harness, the chairman of the publicity and propaganda subcommittee of the House of Representatives, conducted an investigation of the so-called health workshops which have been widely sponsored and participated in by members of various federal organizations. These "health workshops" are designed to mobilize pressure groups in behalf of socialized medicine. Congressman Harness has shown that six

federal departments, bureaus and agencies have been known to participate in these workshops.

I should like to speak briefly on the current Washington scene in Congress which has recently convened. Up to this time more than fifty measures in the medical field have already been introduced. These deal with a number of diseases and subjects such as arthritis, leprosy, epilepsy, multiple sclerosis, bills to provide federal loans to medical students, and a number of other related measures. The bill "S-5" which has been introduced is the new edition of the Murray-Wagner-Dingell Bill. This bill is to be considered in the Senate by the very important Labor and Public Welfare Committee. At present this committee is well occupied with its consideration of the Taft-Hartley law. It is probable, however, that within the next few weeks they will get around to considering the new version of the Murray-Wagner-Dingell Bill.

Several members of the Senate Labor and Public Welfare Committee have expressed their interest in a measure suggested by Gilson Engle, president of the Medical Society of the State of Pennsylvania. In essence the Engle plan provides for the federal support of students in the medical sciences and of their institutions. It provides for more funds and greater authority than the Hill-Burton hospital construction law. It provides for federalization of the Blue Shield and Blue Cross only where "medically indigent" are concerned; it provides for the establishment of a health department with a physician secretary in the president's cabinet in addition to abolition of politics from appointments to Federal Public Health positions.

Capital hill sentiment is mounting for Engle's kind of approach to the solution of our medical problems in lieu of the S-5 bill as it now exists. The twelve-point plan of the American Medical Association is similar to the Engle plan.

Inasmuch as the program of the American Medical Association is being primarily directed at providing voluntary prepayment medical plans as a more desirable type of medical care than that to be derived under compulsory insurance programs, it is appropriate that we discuss the progress being made by these organizations in the United States. To date there are sixty-six plans for prepayment of medical care which have met with the standards of acceptance as outlined by the Council on Medical Service of the American Medical Association. These plans are scattered through forty-two states and the District of Columbia. The remaining states are at this time working on medical prepayment plans which in the course of time will be introduced. Opinion Research Corporation in September, 1948, estimated that 47 per cent of the public is covered by some form of private medical or sickness insurance. In addition to this type of insurance there are a number of commercial insurance companies writing an indemnity type of policy.

In any discussion of proposed socialized medicine, it is well to consider the experience of other countries which have had similar problems and countries which have tried various forms of compulsory health insurance. Of particular interest is the experience of New Zealand.** With the introduction of socialized medicine in 1939 the government compelled everybody in New Zealand to come within its scope and the payment for this stupendous undertaking was provided for by means of direct taxation. Five and one-half cents out of every dollar gross income or salary is collected as a special tax. This amount only partly covers the cost of administration of social security; in addition the fund must be subsidized from the consolidated fund of the government. Approximately a fourth of the government income in New Zealand is expended on social security programs; this equals $60 per head of population. According to the statute which was enacted in New Zealand, every person is entitled "without cost" to himself to such medical attention as is ordinarily given by medical practitioners in the course of general practice. Pharmaceutical benefits are provided "free of any cost to the patient." State hospital benefits are provided "free of cost to the patient." Private hospital charges are subsidized up to $2 per day. The private practitioner's fees are regarded as full settlement of his claim. In the case of specialists, additional fees over and above basic allowances must be recovered from the patient.

The chiropractors are now making representation to be included in this plan.

When a patient in New Zealand visits his medical practitioner "without cost to himself," at the conclusion of his consultation he signs a form;

**This information was obtained from an address given in the United States last year by Dr. A. Lexington Jones, Christchurch, New Zealand.

that form is signed by the physician and directed to the health department for whatever sum is involved. The form is a simple one. The physician's name, the number of visits the patient has made and the total cost appears on it. The claim is signed by the physician and paid without question. The patient is free to visit the physician as many times a day as he wishes, he may visit as many physicians as he wishes, and he may obtain from each physician a prescription which he may have filled "without cost" to himself. He may be signed over to any one of the subsidiary benefits for pension, admission to a hospital, massage, roentgenologic examination and so forth. He may indulge in this pastime among the physicians to his heart's content or until he finally interviews the physician who will do as he bids, give him the medicine he desires and put him in the institution of his choice and place him on the advantageous pension list. He may do all this "without cost" to himself, the one and only condition being that he must be prepared to wait, sick or well, in line among a queue of people on similar business.

A great part of the money which those in New Zealand are taxed is absorbed in the cost of administration, in payment to a large body of civil servants, to physicians for visits that were never necessary and for prescriptions which were given to patients who did not need them. The medical profession has so many consultations that it is impossible for physicians to devote the necessary time to each patient, evaluate his symptoms and give a careful and considered diagnosis.

This system has lowered the status of the medical profession and has lowered its prestige, owing to the known abuses that may be practiced by unscrupulous members. There is no competent check made of medical claims.

It is too early to judge the progress being made under socialized medicine in England. The present all-inclusive program has been in effect less than a year, and reports vary with the philosophy of the reporter. However, physicians agree that there are so many forms to be filled out that it is inconceivable that a British physician can carry on a competent practice without the services of someone to perform his paper work for him. The money provided for a year of the program was exhausted in four months.

In an article in the current issue of the *New England Journal of Medicine,* Dr. William Sweet of the Massachusetts General Hospital reported his observations on socialized medicine in England. He has recently returned from England, where he spent several months working in a medical center.

He has indicated that a British practitioner must see at least fifty patients a day if he has the average panel of 2,000 persons, or at least 100 patients a day if his panel is the maximum of 4,000 allowed. Patients with minor complaints, though they recognize the trivial nature of their complaints, now present themselves. The availability of free conversation with a physician and free medicine is multiplying the number of psychoneurotic and hypochondriac patients who appear.

The labor government requires that a worker absent from his job must present a valid excuse. A note from a physician is desirable. The patient's word must be accepted by the physician, or on subsequent illnesses the patient will call on the physician to make a house call to substantiate his claim.

Many patients wishing to circumvent regulations such as food rationing, restrictions on heat, domestic equipment, transportation and so forth —even the purchase of a hot-water bottle—must possess a government permit, one avenue to which is a physician's certificate of medical need.

Routine laboratory examinations are difficult for the physician, especially the general practitioner, to get. They must be secured through the already swamped clinico-pathologic and roentgenologic departments of hospitals. When much study is required on an interesting problem, the general practitioner has his ardor dampened by the necessity of referring his patient to a consultant.

Failure of a physician to answer an emergency call may not only lose for him the patient but make him liable to serious disciplinary action by the "general medical council" or other appropriate agency.

A physician may order a prosthesis or brace but he may not specify the firm making the appliance. This policy is at present eliminating from the field one firm widely regarded as the best British maker of artificial limbs but which is no favorite of the labor government.

The current waiting list before admission to the hospital of a patient with a presumed brain

tumor is about three months. A request for special neurosurgical instruments to be used in a new neurosurgical procedure was politely denied —eight months later.

The crucial feature of England's difficulty lies in the fact that the responsibility for being healthy has shifted from the patient to the physician.

Dr. A. M. Snell recently had the opportunity to spend a few weeks in England. His was an excellent opportunity to study the workings of English socialized medicine. He has indicated that neither the profession nor the hospitals were yet ready for the scheme. More hospitals and diagnostic centers are urgently needed. Medical personnel will be difficult to obtain since the practice of medicine is not particularly attractive at this moment. There is too much bureaucratic interference. There are delays in all fields, notably supplies. The professional invalid is in his element, as is the compensation seeker. The middle-class groups are unhappy since they cannot afford to pay the tax and have the physicians of their choice, too; they dislike dispensaries. The general practice of medicine is deteriorating into a semi-clerical job, unattractive to any capable man.

The plight of the general practitioner was satirized by the following poem, which appeared in the issue of the *Lancet* for January 22, 1949.

CHAUCER: 1949 MODEL

(*London Lancet,* January 22, 1949, p. 161)

A practisour there was with penne in fyste,
He had four thousand pacions on his lyste
And doctored them right spedely; to each
He gave two minutes, cutting short their speche,
Writing them scripte in Latin most impure.
He had a verray pretty signature
Which none coude rede, but noöne ever tryed.
He had a motor carre in which to ryde
And eke a bagge to hold his stock-in-trade
—Divers certificates of every shade—
These he dispensed with a lavish grace,
Writing the details in the appropriate place.
With these and him his pacions were content.
He had no neede for any instrument.
He took no trouble, but he gave none
So he stood high with high-ups everyone,
Small wonder all came floccynge to his door
He was a parfit general practisour.

Regarding what has happened in Germany, perhaps you have read the article entitled "Nazi Medical Crimes" which was published in a recent issue of the *Journal of the American Medical Association.* This article was written by Dr. A. C. Ivy, whom many of you know. Dr. Ivy stated: "Soon after the Nazis assumed power, they took over the control of the organized medical profession. This control gradually became more and more severe; it was not long before free scientific discussion and criticism was suppressed and scientific medical meetings became infrequent and were poorly attended. Contrary to the precepts of medical ethics, a student had to be or to have been a member of the Hitler Youth Movement. A medical graduate could not obtain an internship unless he was a party member."

In conclusion, one might summarize the feelings of most physicians as they were expressed so well in the recent issue of the *New England Journal of Medicine,* in an editorial entitled "Fish or Cut Bait."

The American medical profession must realize that it is functioning in a world in social revolution, and that slow evolutionary processes of change are not adequate to bring it up to the times and keep it abreast of them. It must understand that the only apparent alternative to such a remodeling of its methods is capture and eventual domination by other forces, that, lofty as their motives may be, have yet but a limited understanding of the traditions, the ideals and the techniques that they seek to control. The profession of medicine must, and must now, become fully awake to its responsibilities, to the dangers which threaten it and to its own strength. It must make up in a few brief months for years lost in the cultivation of its public relations. It must teach a forgetful public what that public owes to it. It must acknowledge openly what it owes to the public and present its plan of payment. It must acknowledge its inertia, its blunders and its former indifference to public opinion. It must show its receptiveness to new ideas, its ability to discuss the common problems with all agencies that are honestly seeking the same goal of service.

There is today one vital consideration for physicians to remember: they must work in harmony, if they are to achieve through their own initiative those things that others believe can be achieved better by methods of compulsion.

ANALYSIS OF ELECTROCARDIOGRAMS OF NINETY-THREE PATIENTS WITH ACUTE RHEUMATIC FEVER

B. F. FULLER, M.D.
Rochester, Minnesota
and
ELIOT YOUNG, M.D.
Boston, Massachusetts

IN THE course of reading electrocardiograms at the Lowry Field Station Hospital, the majority of which were taken on male patients with acute rheumatic fever, several questions arose, the answers to which were not readily available either in the standard texts on electrocardiography or in the current literature. It was observed that (1) a significant number of these patients showed normal electrocardiograms throughout their illness, although they undisputedly had acute rheumatic fever, and (2) many changes were present in the electrocardiograms of these patients other than the prolonged PR interval. T wave changes were frequently seen, especially in the CF_4 position, as well as many other nonspecific evidences of myocardial involvement. Because we were unable to find any recent tabulation of their expected frequency of occurrence, it was felt that a study of the electrocardiograms of a series of patients with acute rheumatic fever would be informative.

For subjects, ninety-three patients with acute rheumatic fever were selected from the records of the Lowry Field Station Hospital, Denver, Colorado, over the period from 1942 to 1946. The charts of all the patients in this series were carefully reviewed in order to establish the diagnosis with as much certainty as possible. Whenever insufficient data were available to make an absolute diagnosis, the chart was rejected. This will be discussed later as a possible source of error in the calculation of the percentage of patients who show electrocardiographic abnormalities.

T. D. Jones' "Diagnosis of Rheumatic Fever"[8] was used as our criterion of diagnosis in selecting the patients to be included in this series.

Complications of acute rheumatic fever, i.e., pericarditis, were cause for exclusion from the series.

The patients all had an electrocardiogram taken on admission to the hospital and at regular intervals thereafter. During the last six months our procedure was to obtain weekly electrocardiographic tracings on all patients under observation for rheumatic fever. During the acute episode an attempt was made to follow each patient even more closely, obtaining daily tracings if necessary. This was especially true if the original tracings showed borderline changes or were normal.

The standard limb leads and the standard apical lead (CF_4) were taken on all of the patients, with the patients in the supine position.

Normal Values Used in Interpretation of Electrocardiograms

Because of the wide divergence of opinion found existing among the various authorities as to both the selection of the limits of normal allowed in the interpretation of electrocardiograms and the amount of significance which should be attached to certain variations from the normal, it is felt that any paper discussing electrocardiographic analysis should be prefaced by a definition of the normal values used by the authors. In general, we tended to be very liberal in our interpretations, using the widest acceptable limits of normalcy as our reference points. At the same time, we regarded all tracings in which the contour and measurements approached the upper limits of normal with suspicion, and these patients were carefully studied both clinically and with serial tracings to further evaluate the cardiac status. In this manner an attempt was made to determine the true significance of the borderline changes in the original electrocardiogram.

Our normal values are listed in detail below.

Rate.—Rates between 60 and 100 beats per minute were considered to be normal. Rates below and above this were considered to be bradycardia and tachycardia, respectively.

Rhythm.—Arrhythmias were diagnosed according to standard criteria.[5,9,10,22]

PR Interval.—A PR interval of .22 seconds was considered to be the upper limit of normal for any single tracing. However, we considered a PR interval of the same duration to be indicative of first-degree heart block if previous or subse-

quent tracings on that patient showed a significantly shorter PR interval.

As an arbitrary figure denoting the division between the normal and the abnormal, .22 seconds agrees roughly with the findings of Stewart and Manning[7,17] and of Graybiel et al.[6] Stewart and Manning find that in the second limb lead a PR interval greater than .21 seconds falls two standard deviations from their mean. They consider this to be of significance, as only 2.5 per cent of normals will fall above this limit. They further state that a PR interval greater than .24 seconds is of great significance, as this falls three standard deviations from their mean. The probability of a normal individual exceeding this is only 0.15 per cent.

Graybiel et al find that in their series of 1,000 normal young aviators, 915 had PR intervals between .12 and .18 seconds and only twelve were of .22 seconds or greater.

This further indicates the often emphasized fact that there are no sharp dividing lines in physiological measurements. All that can be done is to regard an electrocardiographic tracing with progressively more suspicion as it approaches the limits of normal and to attempt to assess its true meaning by further study.

The lower limits of normal were taken to be .10 seconds.

P Waves.—P waves were evaluated according to the criteria listed in standard texts. We were unable to fasten much diagnostic value to the P waves in acute rheumatic fever. Because of the wide variations in contour of the P waves within the normal limits, it was felt that minimal changes were of little significance.

QRS Complex.—We considered .12 seconds to be the upper limit of normal for the duration of the QRS complex in both the limb leads and in the precordial lead. Here again, it is impossible to arbitrarily select any single value as representative of the dividing line between the normal and the abnormal.[6,7,16,17,21] Stewart and Manning[17] found that values in excess of .10 seconds were two standard deviations from their mean, and that values in excess of .12 seconds were three standard deviations from their mean. Graybiel et al found that in their series thirty-eight of 1,000 normals exceeded .10 seconds and that three of 1,000 normals exceeded .12 seconds.[6]

No significance was attached to notching and slurring of the limbs of the QRS complex in the absence of prolonged intraventricular conduction time.

Low voltage was considered to be present in the limb leads only if all of the QRS complexes were less than 5 mm. in height. Low voltage was considered to be present in the precordial lead if the P wave was less than 2 mm. in height.

ST Junction.—(A) Limb leads: An elevation of the ST junction in excess of 1 mm. or a depression in excess of .5 mm. was considered to be abnormal.

(B) Precordial lead: An elevation in excess of 2 mm. or a depression in excess of .25 mm. was considered to be abnormal.

T Waves.— (A) Limb leads: (1) Leads I and II. T waves were required to be positive and of 1 mm. or more in height to be considered normal. Flat, diphasic or inverted T waves were considered as definitely abnormal. (2) Lead III. The T wave in lead III was considered to be of little diagnostic value since it appears normally in either positive, flat, diphasic, or negative form. Even changes in contour of the T_3 occurring in serial tracings were regarded with skepticism unless associated with other changes.

(B) Precordial lead: Diphasic or negative T_4's were considered to be abnormal.

Findings

Total Number of Patients.—Ninety-three males.

Age.—The ages varied from seventeen to forty-one years; 88 per cent were between eighteen and twenty-five years of age.

Past History of Rheumatic Fever.—Thirteen of the ninety-three patients (13.9 per cent) had a past history of rheumatic fever. Two additional patients had a history suggestive of rheumatic fever, but had never had a definite diagnosis made.

Total Number of Patients Who Showed Abnormalities of Any Kind in Their Electrocardiograms.—Of the ninety-three patients, sixty-three showed some abnormality in their electrocardiogram at some time during their hospital stay (67.7 per cent). This figure should be accepted only with the following reservation. Because of the method used in selecting patients, it was necessary to reject any chart which did not have listed the

necessary data to make a diagnosis. Therefore, we feel that we probably rejected an occasional chart of a patient who really had acute rheumatic fever but who did not have enough diagnostic criteria listed to enable us to confirm the diagnosis from his chart alone. This, of course, would make our percentage higher than the true percentage.

PR Interval.—Thirty-seven patients (39.7 per cent) showed abnormal delay in auriculoventricular conduction time. Of these, thirty-one exceeded .22 seconds. The remaining six were of .22 seconds duration. Multiple electrocardiograms of these borderline patients indicated that .22 seconds probably represented an early first-degree heart block for them. Three of these six patients also showed other electrocardiographic abnormalities as confirmatory evidence of cardiac involvement.

Sinus Tachycardia.—Thirty-one patients (33.3 per cent) showed rates in excess of 100 beats per minute. Although sinus tachycardia is of little diagnostic significance in itself, it is of interest to note that in Graybiel's series of 1,000 normal young adults, only three patients showed rates over 100.

Sinus Bradycardia.—Eighteen patients (19.3 per cent) had rates under sixty per minute.

Arrhythmias.—Sinus arrhythmia was not considered. Two patients showed the Wenkebach phenomenon (second-degree heart block), and one patient showed frequent nodal extrasystoles.

P Wave.—Only one patient showed definite P wave abnormality. In this patient the P wave of the second limb lead was coarsely notched and of .16 second duration.

QRS Complex.—(A) Limb leads: None of the patients showed abnormal prolongation of the QRS complex. None of the complexes exceeded .11 seconds. Four patients had low voltage of the QRS^{LL} (4.3 per cent). In none of these did the highest QRS complex exceed 4 mm.

(B) Precordial lead: None of the patients showed abnormal duration of QRS_4. Seven patients (7.5 per cent) showed an R_4 of less than 2 mm. in height. This is probably of some significance, since in a study of 100 normal young adults done by Aagaard and Skubi[1] only one patient showed an R_4 of less than 2 mm.

ST Junction.—(A) Limb leads: Eleven patients (11.8 per cent) showed an elevation of the ST junction over 1 mm. Three patients showed a depression greater than .5 mm.

(B) Precordial lead: Seven patients (7.5 per cent) showed elevation greater than 2 mm. One patient showed a depression in excess of .25 mm.

T Wave Changes.—Thirty-three patients (33.5 per cent) showed T wave abnormality in at least one lead. Twenty-one patients showed abnormality in the T waves of the limb leads. Eighteen patients showed abnormality in the T_4. (Some showed abnormality in both, hence the discrepancy in figures.)

There has been much discussion of the significance of the occurrence of an inverted or diphasic T_4 as an isolated electrocardiographic abnormality. It is true that it may be seen rarely in a patient in whom no apparent explanation can be found for the abnormality (two of Graybiel's 1,000 patients had a diphasic T_4), and that it may be seen somewhat more commonly due to various noncardiac factors in the absence of demonstrable cardiac disease (i.e., generalized toxemia, vasomotor instability, acute abdominal conditions, drugs, et cetera.)[16] However, we feel that it is of definite significance in patients whose history and clinical findings point towards cardiac disease being present. Levy and Bruenn[11] cite several cases in which the T_4 was the only abnormal variant in the tracing, and we have, also, found this to occur not infrequently. Noncardiac factors, of course, must be kept in mind and ruled out.

Another factor frequently mentioned in discussions of the significance of changes in the contour of the T_4 is that of malpositioning of the electrode. However, if one considers only inverted or disphasic T waves as abnormal, it would seem to rule out fairly well the possibility of malpositioning causing the abnormality, since the electrode would have to be placed almost in the CF_2 position to cause inversion in a normal adult subject.

The age of the patient is also a factor to be considered in evaluating the significance of T_4 changes. This is especially true in acute rheumatic fever.

In the present series, twelve of the patients (66.6 per cent) of the total showing T_4 abnormalities, showed other definite electrocardiographic

abnormalties along with the T wave changes. Of the remaining patients, three showed a single diphasic or inverted T_4 as the only abnormality. The remaining three showed one or two minor changes in addition to the T wave change. All of the T wave changes returned to normal while the patients were under observation.

Discussion

Cohn and Swift,[3] in 1924, studied the electrocardiogram of thirty-seven patients with acute rheumatic fever, and made the following observations: (1) auriculoventricular conduction time may be delayed; (2) abnormalities in the QRS complexes and in the T waves may occur; (3) arrhythmias are common. They concluded that these were transitory signs characteristic of cardiac involvement, although not necessarily specific for rheumatic fever. They felt that the changes they described merely expressed derangement of the heart, indicating that it had been affected by the rheumatic process.

Reid and Kenway,[15] in 1928, reported on the electrocardiograms of patients with acute rheumatic fever and confirmed the findings of Cohn and Swift. Several other reports were published at the same time.

One still cannot disagree with the conclusions drawn by these authors. The only point of criticism which can be leveled is that, in the light of present day studies on large numbers of normal subjects, the earlier authors probably defined their limits of normal too rigidly, thereby increasing their incidence of abnormal findings. It is interesting to note that Reid and Kenway reported 42.6 per cent of their patients to have PR intervals over .21, which agrees almost exactly with our findings. However, using the criterion that an increase in PR interval of .02 seconds or more from a previously established baseline indicates an abnormal delay in auriculoventricular conduction time, they report that 92.3 per cent of their patients exhibit such a delay.

None of the changes described is specific for rheumatic fever. Master and Jaffe[12] describe similar changes in other infectious diseases. Rantz, Spink, and Boisvert[14] describe these changes in the electrocardiogram as they occur following hemolytic streptococcus sore throat.

Of the sixty-two patients who showed abnormalities of any type in their electrocardiograms, twenty-six showed normal electrocardiograms the first time studied. Nine of these showed normal tracings the second time studied, and one had a normal electrocardiogram the first three times he was studied. In addition, ten patients showed changes of only questionable significance on the first tracing, whereas subsequent tracings revealed these changes to be early evidences of cardiac involvement. Only twenty-six patients, less than 50 per cent, showed definite abnormality on their first electrocardiogram. This speaks strongly in favor of following every patient suspected of havings acute rheumatic fever with frequent electrocardiograms during the acute phase of the disease.

It is of interest to note that the T wave changes occurred with as high a frequency in this series as did the PR interval changes. It is also of interest to note the many other electrocardiographic abnormalities that may occur in association with acute rheumatic fever.

One patient in our series deserves special mention. He was a twenty-year-old negro male who died on the twenty-seventh hospital day of acute heart failure. During the time he was under observation he had multiple electrocardiograms taken, all of which were completely normal save for a sinus tachycardia. Autopsy, however, showed evidence of extensive myocardial involvement. This indicates that the electrocardiogram is not as sensitive as we would like to have it in detecting minimal (or sometimes even gross) evidence of myocardial disease.

Summary

The electrocardiograms of ninety-three patients with acute rheumatic fever are analyzed and the variations from normal noted.

The relative frequency of occurrence of the abnormalities seen in this series is listed. Thirty-two per cent of the individuals studied showed no electrocardiographic abnormality during their entire illness. Of the remainder, T wave changes occurred with almost the same frequency as did prolongation of the PR interval.

Addendum

Since this paper was written, a similar report by Blackman and Hamilton appeared in the *Annals of Internal Medicine*.[2] Although they restricted their series to those patients having acute rheumatic fever for the first time, their incidence of PR interval changes agreed rather closely with

SKELETAL TRACTION IN THE TREATMENT OF TRAUMATIC ANTERIOR THORACIC INSTABILITY

THOMAS J. KINSELLA, M.D., and ROBERT GLEN BRONSON, M.D.
Minneapolis, Minnesota

THORACIC instability resulting from multiple rib fractures and/or costochondral separations is a well-recognized problem. The disturbance in the physiology of respiration is the real trouble, but it is so well understood in its essentials and so involved in its details that we merely mention it here en route to the following brief discussion of methods used to stablize the unstable thorax and of a case in point from the Fracture Service of the Minneapolis General Hospital.

Increasing the stability of the thoracic cage by taping heavily[1,5] or by supporting bilaterally with sandbags has allegedly helped at times but often, particularly in cases of marked anterior instability, has been inadequate. Towel clips[4] or barbless fishhooks used as instruments of suspension have been more helpful but, because of their sharp points, are more dangerous. Towel clips have the added disadvantage of being relatively dainty instruments, and both tend in too short time to pull out or cut out of the tissues. Jaslow[3] reported encouraging results from the use of one or two large, coarse-threaded closet hooks screwed into the anterior wall of the sternum. There have been suggestions that the Drinker respirator might be used to advantage;[2] but, while we have not had experience with the respirator in such cases, it seems that to bring about adequate respiratory exchange at the cost of irritating motion at the fracture sites, with the grinding together of fractured bone-ends and the possible penetration of pleurae and vessels by sharp bony spicules, is to make an unnecessarily poor bargain.

We write this paper to tell of our satisfactory experience with a blunt, wide-mouthed instrument capable of withstanding prolonged pull in the reestablishment of thoracic stability. It was simply our good fortune to have available such an instrument—a uterine tenaculum previously modified for use in exerting traction on the depressed zygomatic arch (Fig. 1)—when we fell heir to the following case:

A twenty-seven-year-old white woman was admitted to the Fracture Service of the Minneapolis General Hospital following an automobile accident.

Physical examination revealed an unconscious young woman with apparently severe injuries. Blood pressure was 90/45, pulse 88, respirations 22. Her clothing was heavily blood-stained from a large scalp laceration and multiple face lacerations. The central portion of the anterior chest wall was depressed, and multiple rib fractures and/or costochondral separations were palpable bilaterally. Breathing was labored, and on inspiration the sternal segment was noted to retract. A bedside chest roentgenogram showed fractures of the second, fourth, sixth, and eighth ribs on the left, and of the eighth and seventh and probably the sixth on the right. But these were all posterior to the anterior axillary lines so a great part of the sternal instability seemed due to the costochondral junction disruptions. The chest was full of sibilant and sonorous râles, but breath sounds were heard throughout both lung fields and the chest roentgenograms showed no pneumothorax. The abdomen exhibited generalized voluntary muscle spasm but was otherwise negative. The spine and pelvis were intact. The left lower limb was in a half-ring Thomas traction splint and revealed a hematoma anteriorly near the junction of the middle and lower thirds of the leg. A very small scratch in the skin was noted in that area, but no bony points projected through the skin or immediately underlay the scratch.

She presented the shock triad of ashen cyanosis, cold clammy skin and rapid thready pulse. When she reached the ward, she was immediately placed in a steep Trendelenburg position and two units of plasma were started intravenous simultaneously, one in each antecubital vein. A third unit of plasma and 1,000 c.c. of normal saline solution were added as needed, and oxygen per BLB mask was begun. Her wounds were thoroughly cleansed with green soap and water, and sulfa powder was applied; a careful examination of the wound near the left tibial fracture showed it to be only a shallow laceration. Combined tetanus and gas-gangrene antitoxins were given and penicillin was begun. Five hours after admission she was given 500 c.c. of whole blood. After the blood pressure had become relatively stable at a satisfactory level, the wounds of the face and scalp were sutured, and skeletal traction in a Stimson splint was placed on the left lower limb through a Kirschner wire in the os calcis.

But as time went on, the most serious problem became increasingly apparent: how to stablize the essentially free sternal segment in order to provide an efficient respiratory mechanism. Respirations had become more labored and sternal retraction with each inspiration had become more marked. We taped the chest heavily but to litle or no avail. We packed sand-bags along each side of the chest, but her respiratory embarrassment continued. The Drinker respirator was considered but was decided against. Finally we decided to suspend the ster-

From the Minneapolis General Hospital, Minneapolis, Minnesota.

nal segment. We inserted a large barbless fishhook around the inferior border of the costo-xiphoid angle and attached to it about 8 pounds of traction through an overhead block system. The idea was all right but the flesh was literally weak; the hook pulled loose. So the search began for an instrument that could grasp the sternum and hold it firmly. Only a large modified uterine tenaculum seemed adequate; in use it proved most satisfactory. In the accompanying photograph it is apparent that the jaws are somewhat blunted and approach each other at a wide angle. Each of these characteristics is important: the rounded points lessen the danger to the pleurae and the internal mammary vessels as the instrument is introduced, and the wide angle makes a firm grasp possible.

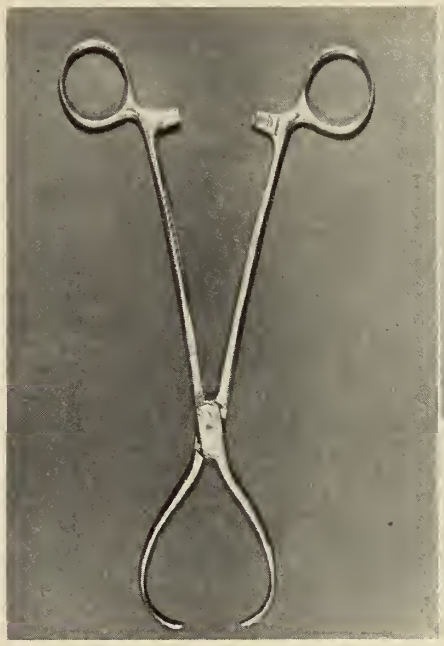

Fig. 1. Uterine tenaculum modified for use in exerting traction on the sternum.

Fig. 2. Tenaculum inserted and exerting traction.

Under local 1 per cent novocaine anesthesia the fishhook was removed and the tenaculum applied, first one jaw being slipped behind the sternum in the fifth interspace and then its fellow inserted also in the fifth interspace but on the opposite side. About 10 pounds of traction was applied through the overhead block system. The inserted tenaculum with traction applied is shown in Figure 2. Her breathing at once became easier, and there was apparently only minor discomfort associated with the traction. Some difficulty with shifting areas of congestion and atelectasis necessitated repeated bronchoscopies and aspirations. Before it became necssary to do a tracheotomy in order to avoid undue trauma to the larynx, the lungs cleared. Eventually, because we found it had begun to slip, we removed the tenaculum and replaced it with two, one with its jaws in the fourth interspace bilaterally and the other with one jaw in the sixth interspace and the other jaw in the costo-xiphoid angle on the opposite side of the sternum. But the method in general and the tenaculi in particular provided most admirably the anterior thoracic stability we sought.

After about ten days the traction was reduced 1 pound each day until, on the twenty-first hospital day, after complete removal of traction had resulted in no respiratory difficulty and had revealed no remaining sternal instability, the tenaculi were removed. The wounds showed no evidence of infection and healed quickly, and the patient recovered uneventfully.

In retrospect, we quite naturally feel fortunate in many things, not the least of which was the failure of the original trauma and resultant sharp bony edges to pierce the parietal pleura on either side. And while we are thinking thankfully of intact parietal pleura, it might be well to point out that the introduction of such instruments as the tenaculi we used should be done with extreme care if that intactness is to be preserved and if the internal mammary vessels are to be spared.

Summary

The problem of traumatic thoracic instability is recognized, and various possible solutions are men-

DETECTION OF EARLY CANCER OF THE CERVIX UTERI BY THE PAPANICOLAOU METHOD

An Analysis of 1000 Consecutive Cases

KANO IKEDA, M.D.
Saint Paul, Minnesota

THE purpose of this communication is to offer an evaluation of the Papanicolaou's cytologic method of diagnosis in early cervical cancer, and to focus attention to an important observation that this method of early diagnosis should be recognized as the most valuable means at our disposal at the present time, of reducing the mortality and morbidity resulting from this condition.

It is not within the scope of this paper to review the fast accumulating literature on this subject, nor is detailed discussion of the technique of the cytologic diagnosis of cancer indicated here. I wish, at this juncture, however, to pay a tribute to the man whose pioneer research into the cytology of the female genital tract had led to the development of a technique for the diagnosis of uterine cancer by the vaginal smear, and who, more than anyone else, is responsible for popularizing the application of the cytologic method in cancer diagnosis. Inspired by his leadership, and following the pattern already set by him, other investigators have devoted their time and facilities in the evaluation of his method, and have repeatedly confirmed his original claims that the vaginal smear method is a valuable aid in the diagnosis of uterine cancer, particularly in its early or incipient stage. Indeed, it may be stated without exaggeration, that since this method of diagnosis has been introduced in practice, literally hundreds of victims of early cervical cancer have probably been cured completely. A tribute is due Dr. Papanicolaou for his persistence and courage in daring to challenge the accepted dictum that a diagnosis of cancer should never be attempted by the cytology of the individual cell alone. Today even the conservative pathologist has come to accept the Papanicolaou method as a useful means of detecting the presence of cancer in man, and to adopt it as one of the major laboratory aids in cancer diagnosis. I have, therefore, purposely used in the title of this paper, the individual name of Papanicolaou to designate the method, rather than an impersonal, if a more scientific term, of cytologic method of cancer diagnosis. It should be emphasized, here, however, that the Papanicolaou stain or method is not specific for cancer cells. Papanicolaou, himself, insists that other staining methods may be used with the same results by those who are accustomed to using them.

The technique[7] of obtaining the smear is relatively simple. No douche or bimanual examination should precede the smear taking. It may be obtained from three separate sources, the vagina (posterior vault), cervix, and the endometrium, all of which Papanicolaou advocates. The vaginal smear contains exfoliated cells from all three areas, and may be obtained by a pipette or a speculum; the cervical smear is obtained by swabbing or scraping the external os and the endometrial smear by means of a cannula (laryngeal cannula). As to the preference for the type of the smear—the cervical or the vaginal—because of its simplicity some prefer the vaginal, which contains the cell types from all three sources. Ayre[1] and others prefer the cervical, claiming that "the cytologic smears taken from the external os of the cervix exhibited a greater concentration of cancer cells." The smear should never be allowed to dry; it should be immersed immediately, while wet, into the alcohol-ether mixture for fixation. This is very important. On this seemingly insignificant point depends the success of the method. Unfortunately, this is not generally appreciated by the referring physician, who makes the smear as he would for bacteriological examination. The staining technique is slightly more cumbersome than the ordinary hematoxylin-eosin method. A few claim that the latter method is just as acceptable. I personally prefer the original Papanicolaou technique. The cells appear more transparent. The delicate nuclear structure seems to stand out more sharply, and cornification is more brilliantly brought out by his stain.

The examination of the smear is time consuming. This is the most trying and unwelcome feature of the whole procedure in an average hospital laboratory, unless a specially trained technician or cytologist is employed to make a preliminary survey or screening of each smear, which is time consuming.

The final diagnosis should rest with the pa-

Read before the Ramsey County Medical Society, St. Paul, Minnesota, March 28, 1949.
From the Pathological Laboraotry of the Charles T. Miller Hospital, St. Paul, Minnesota, and the Department of Pathology of the University of Minnesota, Minneapolis, Minnesota.

thologist or a physician specially trained in cytology. The identification of the cell types is not always simple, as some pathologists seem to have imagined. The expert may puzzle over some atypical cells and finally be forced to cast them into a doubtful class. These atypical cells are frequently found in such inflammatory conditions affecting the female genital tract as incomplete abortion, pyometrium, cervical erosion, chronic endocervicitis. Hyperplasia of the squamous epithelium and squamous metaplasia of the columnar endocervical cells are frequently encountered in chronic endocervicitis. Swollen, altered cells, sometimes with a large vesicular nucleus, are commonly seen on the histologic section, which, on the smear, may resemble malignant cells, and mistakenly so diagnosed or labeled as suspicious. Frankly malignant cells, however, usually stand out conspicuously and offer little difficulty for identification. The criteria given for identifying these cells are well known, namely, the nuclear hyperchromatism, vesicularity, and pleomorphism, the increase in the nuclear cytoplasmic ratio, usually the prominent nucleoli, the thick nuclear membrane, the imperfect differentiation, a tendency to clumping, et cetera.

[1]By inspection in the office.
[2]A small granular area inside the os at the time of biopsy.
[3]Bleeding entirely due to a small piece of retained placenta.
[4]Biopsy done several weeks after the cauterization at the time the smear was taken.

Brief Analysis of Cases

The accompanying table gives, at a glance, the pertinent data concerning ten cases of early cervical cancer. A total of 1093 smears were examined, approximately 80 per cent cervical and 20 per cent vaginal. Ninety-three of the smears were repeats. One thousand patients were represented in the study. Of these, 595 were referred by a group of three gynecologists, as routine smears from their office patients, with five positives, or 0.84 per cent; 204 were referred by the gynecologic clinic of the Out-patient Department (Amherst H. Wilder Dispensary) of the Charles T. Miller Hospital, with four positives, or 1.9 per cent. These two groups of 799 patients gave nine positives or 1.25 per cent. The remaining 201 were referred by several physicians, including a few gynecologists, from cases in which there was an indication for taking the smear. There were some thirty-three smears considered suspicious and repeats were taken; in a few instances, a biopsy was made with a negative finding.

Cancer cells were detected in fifteen cases, or 1.5 per cent, of which five had been clinically diagnosed, either as cancer or suspicious of cancer. One biopsy proven case of treated cancer was reported negative by the smear. The remaining ten cases (1.0 per cent- were unsuspected of cancer. A further analysis of these ten cases follows.

All ten patients were married and multigravids except one, with an average of 3.5 pregnancies. Their ages ranged from thirty to sixty-four years, with an average of forty-one years. This is seven years younger than the usually ac-

cepted average minimum age of forty-eight, at which cancer of the cervix is diagnosed. It is noted that five of them were in their thirties (30, 30, 34, 36, 38) and four others in their forties (40, 45, 46, 48). Excluding Case 1 (sixty-four years) an average age for these nine cases would be 38.5 years. Their presenting complaints were relatively insignificant, intermittent or intermenstrual spotting or bleeding being most common, followed in frequency by vaginal discharge. These symptoms were not considered alarming. In three cases no particular complaints were recorded, having merely been submitted to routine smear. In five instances, the cervix was reported clean and considered negative, on inspection at the office. Some of these patients were recalled in the light of the positive smear, and the cervix were re-examined at the office with a negative finding. One such patient (Case 1) was re-examined under anesthesia, prior to biopsy. When the posterior lip of the cervix was pulled down by the tenaculum, a small ulcerating lesion was discovered and the biopsy revealed an infiltrating epidermoid carcinoma. The patient in Case 3, suffering from irregular bleeding, had a clean cervix from which a biopsy was taken at random. The surgeon performed a panhysterectomy which I did not advise on the strength of positive cytology, and because of the uterine bleeding, without the biopsy report which later was found to be negative. Multiple sections of the cervix from the removed uterus revealed an early epidermoid carcinoma, mostly *in situ,* with an occasional tendency to invasion. Incidentally, the bleeding in this case was accounted for by a small localized area of retained placenta. Five patients showed a slight erosion of the cervix, but only in one (Case 4) had a biopsy been contemplated. In Case 5, the lesion was cauterized at the time the smear was obtained. The subsequent smears from this patient were negative, and the cervix was healed at the time a biopsy was finally taken. It failed to reveal a carcinoma on serial sections. This was the only case in which a biopsy confirmation was not obtained. The reason may lie in the fact that the cauterization of the cervix might have completely destroyed preinvasive carcinoma which was replaced by regenerating epithelium at the time of the biopsy. In Case 10, multiple fibromyomata with a small cervical erosion had been diagnosed, and a hysterectomy was being contemplated.

In all instances, the discovery of a positive smear was a distinct surprise to the clinicians. Only in one case (Case 4) had a biopsy been planned.

While I have distinguished three grades of carcinoma in this study, namely, the invasive, early invasive and preinvasive, it is felt that the distinction between the last two should not be taken too literally, since the sections deal only with a few small microscopic fields, and both processes may not be demonstrated in a given biopsied section, even though they may actually exist side by side. It is possible, though unlikely, that a few additional positive cases may have escaped the recognition in this study.

Discussion

The present report of successful detection of malignant cells in ten cases of early or preclinical cancer of the uterine cervix in 1000 smears is offered, first, as another addition to the many reports already published in support of the claims of Papanicolaou and his followers, that the exfoliative cytologic method is a valuable aid in the field of cancer diagnosis, and secondly, as a concrete evidence that cancer of the cervix can be diagnosed in its early or incipient and curable stage. The latter, I believe, should be recognized as a major advance in cancer diagnosis in recent years, and should receive the due emphasis it deserves in the evaluation of this method. Most of the publications on the subject have dealt with the statistical analysis of the results obtained in a series of patients, emphasizing, primarily, a high degree of accuracy in diagnosis. Few have placed the primary emphasis on the second and equally important feature of this method, namely, the detection of early or incipient, or preclinical cancer of the cervix, often in lesion-free or symptomless patients, who would otherwise be dismissed as free of the disease. The same patients would return sooner or later with the clinical symptoms and signs of cervical cancer. This may take several years—as many as twelve years. Chances of cure would thus be greatly reduced.

The incidence[6,8] of carcinoma *in situ* of the cervix is variously estimated from .29 to 3.7 per cent. The latter figure probably more nearly approximates the actual frequency, since it was obtained from 1200 whole cervices removed for other gynecological conditions. Nearly half of these patients are said to be symptom-free and about 80 per cent of them show an insignificant

lesion of the cervix commonly seen in multiparous women.[5] The average age in which the lesion is recognized is thirty-six to thirty-eight years, estimated to be ten to twelve years younger than that in which clinical cancer is diagnosed.[9] Therefore, with this method expertly and extensively utilized, the incidence of early cervical cancer should rise materially, and the expectations for complete cure should be vastly improved.

As to the preference for the type of smear, Ayre[1] and others, as already noted, prefer the cervical smear. Foote and Li[3] found, of the eighteen cases of intra-epithelial epidermoid carcinoma, fourteen positives were obtained by the cervical smear, and nine by the vaginal smear, indicating the greater efficiency of the former in their hands. My own experience agrees with the latter. I personally feel that we can obtain more reliable and suitable smears by the direct visualization of the cervix.

Pertinent would also be the data which might throw light on the comparative value of the biopsy and the cytologic method in the daignosis of early, preinvasive cancer of the cervix. A few of such data are now available. Fremont-Smith, Graham and Meigo[4,5] reported that of thirty such cases, the initial vaginal smear was positive in twenty-three, while the initial biopsy in twenty-seven of the thirty patients was positive in thirteen, and questionable in four. Graham, Sturgis and McGraw[5] reported that of the sixteen cases of carcinoma "in situ" in 181 positive cases, the first biopsy failed in eight (a 50 per cent failure) and the first smear failed only in two (a 12 per cent failure). Other investigators are reporting similar experience. In our experience, of the ten smear positive early cases, the first biopsy failed in two. These reports seem to indicate the superiority of the cytologic method over the biopsy in detecting early or incipient cancer. The reason seems obvious, the former includes the exfoliated cells from the entire cervical surface at the os, while the latter takes a small sample from a corner of the cervix, which may happen to be free from the tumor, as in our cases. To overcome this shortcoming, a multiple biopsy or a "ring biopsy" by means of a cone knife has been advocated,[2] allowing multiple histologic sections.

Summary

A brief discussion of the technique of obtaining the smear for cytologic diagnosis of cervical cancer and of the cytology of such smears is presented, and a short critical analysis of ten unsuspected positive cases, routinely detected from cervices free of a demonstrable lesion, or showing only a minor erosion, in 1000 patients, is given. It is pointed out that the cervical smear seems to yield more positives than the vaginal in given series in the hands of the average examiner. It is further pointed out that the cytologic method, originally developed by Papanicolaou, or modified by subsequent investigators, appears to be more sensitive in detecting early preclinical cancer of the cervix than the conventional biopsy.

In conclusion, it should be re-emphasized that the cytologic method is now well established as a major laboratory procedure in cancer diagnosis. A positive vaginal or cervical smear should never be ignored. It should be confirmed by one or more repeats, and by biopsy. A negative smear does not exclude cancer. Since the only guarantee, if any, for the cure of cancer of the cervix, at the present time is its earliest possible recognition, and since the cytologic technique has satisfactorily demonstrated its greater effectiveness, in competent hands, in detecting early or preclinical cervical cancer than any other method known, and since the routine biopsy in office practice is neither indicated nor practical, the Papanicolaou method of cyto-diagnosis or any of its modifications may profitably be employed in the routine gynecologic practice to aid in the discovery of the cases of early cancer of the cervix uteri which may otherwise be overlooked. Universal application of this method in cancer detection centers and in dispensary clinics seems to be the next step which will be demanded of the medical profession.

FACTORS IN THE DIAGNOSIS OF SQUINT

VERNON L. LINDBERG, M.D.
Minneapolis, Minnesota

IN this discussion only one type of squint will be considered, namely, monocular convergent squint. This is one of the most common muscle problems found in infancy and childhood, and it deserves special attention because of its many unique features.

By way of definition, this is a muscle imbalance in which it is always the same eye that turns in. It is found in children who have a poor fusion faculty, and it is usually associated with a far-sighted refractive error. It occurs chiefly from the first to the third years of life. Amblyopia or "disuse blindness" invariably develops in the squinting eye, if the child is not treated, and the end result is complete absence of binocular vision.

Whenever the question of the cross-eyed child arises in any discussion between the physician and the opthalmologist, the eye man is frequently asked: "At what age do you want to see these cases?" The answer is usually: "As soon as a definite diagnosis of squint is made." The next question could logically be: "Well, why? You're not going to operate these infants at the age of six months or a year. What's the rush?" And this latter is a good question, because it brings up the subject of the nonsurgical treatment of squint. This is closely tied in with the importance of early diagnosis and institution of early treatment in the case of the cross-eyed child.

I'd like to say a few words about some of the problems and pitfalls the general physician encounters in trying to establish a diagnosis of squint. In most cases when a parent becomes alarmed about whether his child has a crossed eye, he turns first to the pediatrician or family physician, rather than to the eye man for advice. The attitude that the physician takes toward the problem may have a very profound influence upon the child when he later reaches adult life. Of all pediatric eye conditions, squint assumes the greatest importance because of the relative frequency of occurrence. The family physician has a great responsibility in the handling of this problem and in the advice that he gives to the parent. He can err in both directions and to both extremes.

Read at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1948.

There are many unfortunate features about the average squint case which makes it a ripe thing for mismanagement. First of all, squint is not a painful thing to the child. Any diplopia which may occur is usually transitory and soon disappears. The deviation of the eye is usually intermittent at first and present only at times when the child is extremely tired. In many instances the parent and the doctor are prone to look at the problem more as a cosmetic one. Actually the disfigurement is only one phase of the matter.

A comment that has been used by some physicians, and one which I would like to condemn heartily at this point, is that the child, as it grows older, will gradually grow out of it. Unfortunately, when a doctor makes this statement, he is too often stating a fact. In many untreated cases of squint, the deviation becomes less marked and the eye which turned in originally, gradually turns out by the simple expedient of the child becoming blind in the deviating eye—amblyopia ex anopsia.

This amblyopia, if allowed to persist beyond the fifth year, ordinarily cannot be treated effectively. If the child does not undergo treatment, or if the treatment is delayed until a late date, the result is markedly reduced vision in one eye and a complete absence of binocular vision. These two features are usually more serious than the cosmetic defect which persists and which can easily be remedied by corrective surgery at any date. An untreated case of crossed eyes, in which it is the same eye which is always convergent, usually ends up with the fixing eye seeing normal, 20/20, and the crossed eye seeing as bad as 20/400. After the age of five or six years the central vision in the squinting eye is usually irretrievably lost and the process cannot be reversed. Before this age, however, measures can be instituted to recover the lost vision. Hence, the importance of the early diagnosis and treatment of squint.

My remarks here are not directed toward the case in which there is a marked crossing of the eyes and where the diagnosis of crossed eye is obvious, but my suggestions are intended for the case where there is a questionable or slight crossing of the eyes.

When the infant or child is brought for the first time to the physician's office and the question

of squint arises, the physician first examines the patient by inspection. The examination is usually difficult because the child is at one minute on the

Fig. 1. Photograph of adult with normal, straight eyes. It illustrates how an equal amount of sclera or "white" of the eye shows medial and lateral to the cornea in each eye, when the eyes are in primary position gazing directly ahead.

mother's lap, the next minute on the floor, the next minute across the room, and presently pulling books off the physician's desk. If an attempt is made to immobilize the subject, the child often resists, cries out, and closes its eyes forceably, thus defeating the entire purpose of the examination. I mention this activity, because when a child is observed under these conditions its eyes are being noted not only in the primary position but more frequently when they are turned one way or the other.

The amount of sclera, or white of the eye, which shows on each side of the cornea has a lot to do with the appearance or simulated appearance of a crossed eye. Ordinarily when a normal individual is viewed with the eyes in primary position, almost an equal amount of white shows on each side of the cornea, and a mental note is made of the fact that the eyes are straight (Fig. 1). However, if less white of the eye shows medial to the cornea than laterally, as is the case with a crossed eye, it gives the eye the appearance of turning in. (Fig. 2)

I call attention to these facts because there is a condition in infants and young children known as "epicanthal folds" which simulates the appearance of true squint. The epicanthal fold is a small fold of skin arising from the upper eyelid and insert-

Fig. 2. A case of monocular convergent squint. The right eye is "fixing," and the light reflex falls in the midline of the right cornea. The left eye turns "in," and it can be seen that the reflex falls lateral to the center of the cornea, indicating that the left eye is actually "crossed." It should also be noted that the amount of sclera exposed lateral to the left cornea greatly exceeds the amount of sclera visible medially on the left eye.

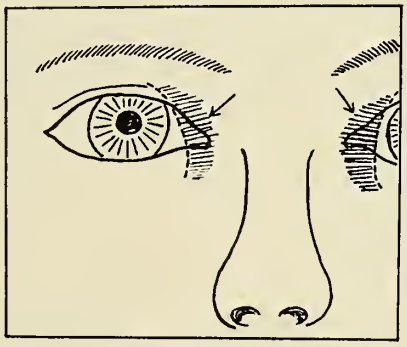

Fig. 3. Epicanthal folds (diagrammatic representation). Shaded areas (indicated by arrows) represent the epicanthal folds which hide the medial sclera and inner canthus.

ing into the side of the nose medial to and below the inner canthus (Fig. 3). This fold of skin will often hide the inner canthus entirely, and will also thereby hide a good portion of the medial sclera.

When a child with this condition is observed, especially if the eyes are not in the primary position, the eye which is looking across the nose will appear to be turned in markedly, and it gives the appearance of being a true case of crossed eye (Fig. 4). Because epicanthal folds usually occur bilaterally, either eye at different times may ap-

Fig. 4. Three views of a patient with epicanthal folds which simulated a true squint.

(*A*) Eyes directed slightly to the patient's right. Note how *left eye* appears to be crossed.

(*B*) Eyes directed slightly to the patient's left. In this position it is the *right eye* which appears to be crossed.

(*C*) With eyes in the primary position, it will be noted that the light reflex falls in the exact center of each cornea, indicating that the eyes are actually not crossed. (Corneal Reflex Test—Hirschberg)

pear to be turned in, depending upon whether or not it is looking across the nose at the physician. In order to minimize the effects of these epicanthal folds, the skin over the dorsum of the nose can be grasped between the forefinger and thumb, or with a pair of blunt forceps, and it will be readily seen that the eyes appear to be much less crossed and more normal in appearance. This procedure exposes the normal amount of sclera which is ordinarily seen medial to the cornea.

It is thus seen that comparing the amount of sclera which is showing medial or lateral to the cornea is not a reliable method of judging whether squint is present. However, we are constantly subject to this error unless we consciously guard against it.

In order to avoid this pitfall in diagnosis, a simple test known as the "Hirschberg corneal reflex test" can be carried out which will usually give the true information immediately. A small point source of light, such as an ophthalmoscope bulb, can be used and held at a distance of three feet or more from the child's eyes. This light can be turned on and off to attract the child's attention and the reflection of the light on the cornea may be observed. If this reflection lies in the center of the pupil in each eye, regardless of how crossed the eyes otherwise look, the child has normal, straight eyes (Fig. 4 *C*).

Another test which is a little more difficult of performance and requires greater co-operation from the child can be carried out. This is known as the "cover test." This procedure is based on the fact that, normally, eyes directed at a distant object do not deviate under cover. The child's attention is drawn to a distant light or object, and one eye and then the other is alternately covered with a small piece of paper or the examiner's hand. As the hand is moved from one eye to the other, the eye which is being uncovered is observed. If a movement either out or in is noted, a muscle imbalance is usually present. Using this test, the imbalance noted may be either a manifest deviation, as is the case with true squint, or it may be a latent imbalance which is commonly known as a "phoria."

Each eye can be separately covered also, and this will result in a lateral movement of the fellow eye, if the fixing eye has been covered in a case of convergent squint.

Where epicanthal folds are present and causing the appearance of crossed eyes, the parents can

be reassured that these structures usually disappear as the face and head enlarge during normal development.

If on inspection the eyes appear to be normal and straight, the parents should be asked about the constancy of the squint, because it is always possible that the deviation of the eye does not occur during examination. In this case it is well to reserve your judgment or opinion and have the child return for another visit. The parents should be instructed to bring the child back when he is tired or fatigued, because this is the time that transitory squints are more prone to be present.

As has already been mentioned, the deviating eye usually suffers a reduction in visual acuity. If the history is obtained that it is always the right eye that turns in, and if it can be demonstrated with the illiterate "E" chart that the vision is reduced in the right eye over that of the left eye, then the case should be looked upon very definitely as a true monocular squint. It is this type of case that should be referred at the earliest possible date to the opthalmologist. Refraction should be carried out after the use of atropine in the eyes, and a full correction, in the form of glasses, of the far-sighted refractive error should be given. This procedure, if carried out early in the case, results in straight eyes in over 50 per cent of the cases without any surgical intervention. If, however, full correction of the far-sighted error does not result in parallelism of the eyes, surgical correction is instituted.

If amblyopia can be detected by the ophthalmologist, full time occlusion of the good eye is instituted immediately, and very often results in restoration of vision in the eye which is turned. To be effective, occlusion must be carried out during all the child's waking hours, and, for this reason, it is important that this type of treatment be instituted before the child begins school. Once classes have begun, it is impossible to carry on an adequate program of occlusion of the fixing eye, because the child does not have enough vision in the squinting eye to carry on normal activities in the classroom.

The ideal result in this type of case would be a pair of straight eyes with normal vision in each eye and a normal relationship between the two eyes in the form of true binocular vision. This would be a functional as well as a cosmetic result. In many cases, however, too much time elapses before treatment is instituted and the child ends up with an amblyopic eye. The value of cosmetic surgery in itself should not be minimized, because a cross-eyed child quickly develops personality changes and a feeling of inferiority as the result of the cruel remarks of his or her playmates. This is especially true once the child starts attending school and is another important reason why the eye should be straightened if possible before the child reaches school age.

In summary, monocular convergent squint often presents a problem in early diagnosis. A fairly common condition known as "epicanthal folds" has been shown as a source of error in determining the presence of squint. The "corneal reflex test" and the "cover test" have been described and suggested as aids in detecting cases of "false" squint. Two important reasons for early diagnosis and treatment of this condition before school age have been indicated.

SKELETAL TRACTION IN THE TREATMENT OF TRAUMATIC ANTERIOR THORACIC INSTABILITY

(Continued from Page 487)

tioned. A case of multiple bilateral rib fractures and costochondral junction separations, resulting in an unstable sternal segment with consequent respiratory embarrassment, is presented, together with the description of a method of re-establishing thoracic stability by suspension of the sternal segment, using modified uterine tenaculi.

PERIRECTAL ABSCESS PRODUCING SYMPTOMS OF GENERALIZED PERITONITIS

WILLIAM C. BERNSTEIN, M.D.
Saint Paul, Minnesota

ABSCESSES involving the perirectal surgical spaces other than the ischiorectal fossae are relatively few in number. Patients suffering from abscesses of the supralevator or pelvirectal spaces and of the posterior or retrorectal space are usually profoundly ill and in severe pain. Fatalities have occurred from abscesses in these areas due either to sepsis from the original abscess or to peritonitis following rupture into the general peritoneal cavity. Irritation of the pelvic peritoneum from an underlying abscess cavity may produce the symptoms of a true peritonitis without actual involvement of the peritoneal cavity itself. A case which produced symptoms of peritonitis is presented in this report.

Case Report

C. M., a mulatto, male, aged forty-one, was admitted to the Veterans Hospital in Minneapolis on the evening of January 24, 1948. The patient stated that approximately ten days previously he began to have severe pain in the rectum when he coughed and when he had a bowel movement. He consulted his physician who prescribed penicillin, rectal suppositories and hot packs. The patient continued to work but became progressively worse from day to day. During this period he had a fairly good appetite, but his bowels became constipated and he vomited on one occasion. For several days before admission to the hospital his bowel movements were accompanied by excruciating pain in the rectum.

On the day of admission to the hospital the patient became very ill and complained of severe pain in the lower part of his abdomen and of a constant severe pain high in the rectum. His temperature on admission was 101 degrees; the pulse was 108; respirations were 24 per minute.

The patient appeared acutely ill, and it was noticed that there was splinting of the abdominal muscles during respiration. The abdomen was mildly distended and a fairly marked degree of muscle rigidity was present over the entire abdomen. Extreme tenderness was elicited over the lower half of the abdomen and rebound tenderness was present.

Inspection of the buttocks revealed no abnormal findings and palpation of the tissues over the ischiorectal fossae did not elicit signs of an underlying abscess. Not until deep pressure was applied did the patient complain of pain or tenderness.

A digital rectal examination revealed the presence of a large, painful induration involving the rectal walls anteriorly, laterally and posteriorly. A definite feeling of fluctuation was present which extended to a higher level laterally than it did either anteriorly or posteriorly.

The general physical examination was otherwise entirely negative. An upright x-ray plate of the abdomen revealed no evidence of obstruction or perforation. The x-ray of the chest was negative. Routine laboratory studies of the urine and blood were negative.

A diagnosis of perirectal abscess involving the supralevator spaces and a possible involvement of the retrorectal space was made. The patient was taken to the operating room where spinal anesthesia was given and the right ischiorectal space was unroofed. Pus was not encountered until the levator muscles were reached. At that point an abscess was encountered which contained a very large quantity of pus. The finger which was put into the abscess cavity could be directed to an extension of the cavity posteriorly through the post-anal space and into the left ischiorectal fossa. The left ischiorectal fossa was then uncovered and a communication established with the deep abscess on that side.

No further attempt was made to explore the supralevator space at that time. The overhanging edges of the abscess cavities were trimmed away, thereby creating two large wounds which would stay open without packing. A finger inserted into the rectum at this time revealed the complete disappearance of the mass previously described.

The patient was then returned to the ward, and by the next morning his temperature was normal and he was free of pain. That evening his temperature reached 100.2 degrees and thereafter it was normal. Routine postoperative rectal care with hot sitz baths was given, and the patient was discharged on February 9, sixteen days following the operation.

On March 23 the patient was readmitted for treatment of his fistula. Operation was performed on the following day, and a rather extensive fistula was found. No difficulty was encountered in laying open the entire tract which had its primary opening in the posterior midline crypt and which involved the two supralevator spaces as well as the posterior rectal space. The patient was discharged from the hospital on April 26, approximately four weeks following operation. He returned to work at that time, but healing of the fistula wound was not complete until June 15, 1948.

Comment

A case of bilateral, supralevator, pelvirectal abscess which produced symptoms of peritonitis is presented. The abscess was drained through the ischiorectal fossae, although these spaces were not directly involved. Complete disappearance of the symptoms of peritonitis, which may or may not have been due to actual involvement of the peritoneum, followed the drainage of the abscess.

Read at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1948.

History of Medicine In Minnesota

HISTORY OF MEDICINE IN NICOLLET COUNTY

(Continued from April issue)

1809-1900

Jared Waldo Daniels, the son of Dr. Asa Daniels, was one of the new physicians who began to practice in St. Peter in 1890. He had received his medical training at Rush Medical College and at Columbia University. He served on many local boards and belonged to local and state medical fraternities. James H. Bowers, a homeopath, also practiced in St. Peter for a few years. A Dr. Sweet from Kasota opened a drug store in St. Peter. In the town of Nicollet, C. Wilbor Ray, an eclectic physician, succeeded Dr. Wicke, whose stock of drugs he purchased from the doctor's widow. In St. Peter, George Ranson succeeded Dr. Collins, who died in 1898. Ranson himself died suddenly about a year later. He was succeeded by Fred P. Strathern. There was also a Dr. Caldwell from St. Paul who spent a short time in the town.

A number of new physicians came to the State Hospital for the Insane. The following list included those who were there from the date of its organization up to 1900.

Superintendents

Samuel E. Schantz.....November, 1866—August, 1868
Cyrus K. Bartlett.....November, 1868—January, 1893
Harry A. Tomlinson.....January, 1893—October, 1912

Assistant Physicians

Jacob E. Bowers.....December, 1867—January, 1879
John E. James.....June, 1876—December, 1891
Thomas J. Naylor.....February, 1880—May, 1881
W. A. Jones.....May, 1881—October, 1883
George W. McIntyre.....October, 1883—May, 1884
Arthur F. Kilbourne.....May, 1884—June, 1889
George W. McIntyre.....(Second term) July, 1889—May, 1893
Edward M. Flint.....February, 1890—May, 1893
Harry A. Tomlinson.....December, 1890—January, 1893
Nathan M. Baker.....May, 1893—August, 1895
C. A. Erdman.....May, 1893—June, 1893
Gustave A. Chilgren.....June, 1893—August, 1898
Ella B. Everett.....September, 1893—September, 1896
Thomas R. Foster.....October, 1893—May, 1905
W. H. Darling.....September, 1895—January, 1908
Mary E. Bassett.....September, 1896—July, 1898
Abraham F. Strickler.....June, 1898—May, 1899
O. M. Justice.....May, 1897—May, 1898
C. F. Tuomy.....September, 1898—September, 1906
Donald A. Nicholson.....May, 1899—December, 1904
M. E. Ranson.....July, 1898—June, 1900

Scarlet fever appeared in a mild form during the nineties, particularly in the early years. There were a few fatal cases each year, most of them occurring in Nicollet, Courtland and Brighton. Diphtheria was also reduced, to a very marked extent, in both the number of cases and their virulency. Most of the cases were outside of St. Peter. It was probably at its worst in 1891 when there were eleven deaths in Lafayette. In 1890 there were a number of cases of typhoid in St. Peter and, in 1896, there was a mild epidemic of measles. Compared to the preceding ten years, the health of the county underwent a remarkable improvement.

Dr. Skinner, writing in 1890 on the subject of scarlet fever, was of the opinion that mild epidemics of the disease should have no interference. He held that it was better to have a mild case and then be safe forever. He based his reasoning on the analogy that immunity to smallpox is gained by vaccination—merely giving a person the disease in a very mild form.

About this time Dr. Skinner rented four extra rooms in the Amundsen Building and fitted them up to serve as the first private hospital in St. Peter. According to his advertisement, surgical, medical or lying-in cases were admitted and patients might employ any physician they chose. A private telephone line connected the doctor with Kasota, in Le Sueur County, so that he drew patients from that quarter too.

Doctors Skinner and Merritt served as county coroners and, in St. Peter, Doctors Collins and McIntyre served as health officers.

New members of the Minnesota State Medical Society included the following physicians who were practicing or had practiced in Nicollet County during the nineties: E. N. Flint (1892), G. W. McIntyre (1892), Elizabeth C. Mallison (1892), H. A. Tomlinson (1893), C. M. Skinner (1893), J. G. Erickson (1893), J. W. Daniels (1893), Nathan Baker (1892), G. A. Chilgren (1894), D. B. Collins (1894), George Ranson (1897), Ella B. Everett (1897), and E. P. Strathern (1899).

New members of the Minnesota Valley Medical Association included: J. W. Daniels, C. M. Skinner, N. M. Baker, G. A. Chilgren, H. D. Valin, T. R. Foster, E. B. Everett, and H. A. Tomlinson. Doctors McIntyre, Collins, Tomlinson and J. W. Daniels also belonged to the Southern Minnesota Medical Association. C. Wilbor Ray belonged to the State Eclectic organization.

In January, 1894, the Nicollet County Medical Society was organized and Doctor Chilgren was selected as permanent secretary. The group planned to meet on the last Saturday of every month and to have a paper on some subject of interest presented at each of these monthly meetings. Some of the first reports included an essay on diphtheria by A. W. Daniels: "The Artificial Feeding of Infants," by Dr. Merritt; "The Etiology and Prophylaxis of Tuberculosis," by J. W. Daniels; "Water, in Health and Disease," by Dr. Skinner; "Hysteria," by Dr. Tomlinson. Others who were present at the first meeting were Doctors McIntyre, Everett, N. M. Bauer, Collins, Foster and Wicke.

The Nicollet-Le Sueur County Medical Society was not organized until 1903. The first meeting was held in St. Peter and Dr. Tomlinson was the first president.

Nicollet County Physicians

Anderson, C. A., was a physician at the state hospital in St. Peter in 1893 or 1894.

Baker, Nathan Morton, was born in Nicollet county, in 1859. He attended school in Le Sueur County and in St. Peter and was graduated from the University

of Minnesota in 1884, with the degree of Bachelor of Arts. He taught school and was a chemist for the State Board of Health. He was graduated from the medical department of the University of Pennsylvania in 1889 and, in November of the same year, was appointed assistant physician at the State Hospital for the Insane at Rochester. He remained there until May, 1893. At this time he was appointed first assistant to Dr. H. A. Tomlinson at the St. Peter Hospital. He served at St. Peter for two years, then moved to Spokane, Washington, where he located permanently. Dr. Baker was a member of the Nicollet County Medical Society, serving as president, and also listed membership in the American Medical Association and the Spokane Board of Health.

Bartlett, Cyrus Kilhune, was born in Boxford, Massachusetts, in 1829. He studied under private tutors before entering the Harvard Medical School, from which he was graduated in 1852. He practiced medicine at Charlestown, Massachusetts, from 1852 to 1858, when he was appointed assistant superintendent of the St. Peter Hospital for the Insane, succeeding Dr. S. E. Schantz. In 1892, after twenty-four years of successful service, he resigned and moved to Minneapolis where he practiced his specialty of mental and nervous diseases until his death, in 1911. Dr. Bartlett was a member of the Minnesota Valley Medical Association, serving as its president in 1882, and the Minnesota State Medical Association.

Bassett, Mary Elizabeth, was an assistant physician at the St. Peter Hospital from September, 1896, to July, 1898. In 1899 she married Dr. C. W. Bray in Saint Paul and moved to Biwabick, Minnesota.

Bolon, V., was born in Hanover, Germany, in 1817. He came to the United States in 1845. During the Civil War he served as assistant surgeon in an Illinois regiment. In September, 1878, he located in St. Peter, specializing in eye and ear work and recommending himself as a *geburts-helfer*. He died August 6, 1881, following a paralytic stroke.

Bowers, Jacob Eton, was born in Berlin, Ontario, Canada, in 1811. He attended the Berlin grammar school and Toronto University where he received his Bachelor of Arts and Master of Arts degrees. He then entered the University of Michigan and received his medical degree in 1868. He immediately accepted the position of assistant physician at the St. Peter Hospital, under Dr. S. E. Schantz, beginning work in April. When Dr. Schantz died, Dr. Bowers served as acting superintendent until the arrival, five months later, of Dr. C. K. Bartlett. In 1878 he was appointed superintendent of the Rochester Hospital for the Insane and served until October, 1889, when he moved to Duluth. He practiced his specialty of mental and nervous diseases until 1906 when he retired from practice, making Duluth his home. He was a member of his county medical society, the Minnesota State Medical Association, and the American Medical Association.

Bowers, James H., was graduated from the Chicago Medical College in 1885. He practiced homeopathy, locating in St. Peter in May, 1891, and remaining until January, 1894, when he moved to Riceville, Iowa. From 1897 until 1899 he was in Owatonna.

Bullious, L. H., was graduated, in 1862, from Harvard University. He came to Minnesota because he was suffering from tuberculosis, and located in St.

Peter, sharing an office with Dr. A. W. Daniels. In making a call, he was thrown from his cutter and broke his leg. As a result, his health became worse. He returned to Massachusetts, where he died in 1863.

Barthelow, Roberts, was the third post surgeon at Fort Ridgeley. This was sometime between 1853, when Dr. A. W. Daniels left, and 1861, when Dr. Alfred Mueller was appointed. He was born in 1831 and died in 1904. He was a surgeon in the army from 1856 until 1864 and took part in expeditions to Utah, New Mexico and the western plains. At the outbreak of the Civil War he was attached to the military post at Fort Bridger, Santa Fe, New Mexico. Later he was in Washington. He taught in one of the medical schools in Cincinnati and later was a professor at the Jefferson Medical College. He authored *Materia Medica and Therapeutics,* long a popular textbook.

Caldwell,———, of St. Paul, took over Dr. C. W. Ray's practice in Nicollet while the latter was in Boston during the summer of 1899.

Catlin, Hiram Wesley, was the first physician to locate in Nicollet County, if physicians employed by the government and residing at the fort are exempted. He was born on a farm in Washington County, Indiana, November 27, 1820. At the age of seventeen, he started to study medicine. He was graduated from the Louisville Medical College in 1846, enlisted in a volunteer regiment and served one year in the Mexican War. He took part in leading battles under General Taylor and his knowledge of his profession rendered him useful in the absence of the regular surgeon. He returned and practiced in Georgetown, Indiana. He was a member of the Indiana legislature in 1853. In 1855 he came to St. Peter, where he practiced until his death in 1861. His son and grandson both took up the practice of medicine.

Catlin, T. J., practiced in St. Peter in 1874. He is probably the same Dr. Catlin who, in September, 1881, came to St. Peter, presumably from Delano, Wright County. In November of the same year he returned to Delano.

Chilgren, Gustave Arthur, was born in Lake Prairie township, Nicollet County, in 1865. He was reared on a farm and attended district and St. Peter schools and the University of Minnesota, which he entered about 1884. After graduation, he taught school for a while, then entered the medical department of the university and received his degree in 1892. In August, 1893, he began his work as assistant physician at the St. Peter Hospital for the Insane. He remained until May, 1898, when he resigned to accept the position of assistant superintendent of the South Dakota Hospital for the Insane at Yankton. Six months later he moved to Sauk Rapids, Minnesota, where he practiced for seven years. About 1907 he moved to Burlington, Iowa. Dr. Chilgren was a member of the Nicollet County Medical Society, the Minnesota Valley Medical Society and the Minnesota State Medical Association.

Clark, E. F., resided in St. Peter at an early date. From 1856 until his death, in 1879, he was in Winona.

Collins, Daniel B., was born in Dane county, Wisconsin, in April, 1848. When six years old, he moved, with his parents, to Milton, Wisconsin. Here he attended school and college. He gave his services to his country in the latter

part of the Civil War. In 1871 he was graduated from Rush Medical college and, in the same year, commenced practice in St. Peter, with Dr. A. W. Daniels. In 1876, he moved to Cleveland, Le Sueur County, where for two years he was examining surgeon for pensions. From 1878 until his death, February 14, 1898, he practiced in St. Peter. In 1887 he was appointed a member of the State Lunacy Commission, which position he held until his death. He was several times health officer and city physician, and was surgeon for the second regiment, Minnesota National Guard. During 1890, 1891 and 1894, he attended medical lectures in Chicago and New York. He was a member of the Nicollet County Medical Society, the Minnesota Valley Medical Society, of which he was once president, and the Minnesota State Medical Association. He was also a member of the Military Surgeons of America, the GAR and numerous fraternal orders.

Cosner, Isaac, was one of the first homeopaths to locate in Nicollet County. He came to St. Peter in November, 1866, from Illinois, and remained until 1887 when he moved to Saint Paul. He died January 3, 1888. He was coroner of Nicollet County in the early seventies.

Daniels, Asa Wilder, was one of the first physicians in Nicollet County and became one of the most prominent members of his profession in that locality. He was born in Stratford, New Hampshire, January 15, 1829. He was reared on a farm, attended the public schools and Lancaster Academy. He moved to Boston with his mother and studied medicine there under the direction of his uncle. Later he taught physiology and anatomy. After two years at the Medical College of Ohio, at Cincinnati, from which he was graduated in 1853, he was appointed assistant surgeon at Fort Ridgely, in the western part of Nicollet County. A few months later he was appointed resident physician at the Lower Sioux agency in Redwood county. In July, 1861, he moved to St. Peter, where he practiced until he moved to Pomona, California, in 1908. At the Indian outbreak of 1862 he went to New Ulm with the volunteers commanded by Major Charles E. Flandreau where, with Dr. Otis Ayer of Le Sueur, he gave valuable surgical aid to the wounded. Dr. Daniels held the position of pension surgeon for several years and was Nicollet County physician during the seventies. He was also a member of the first State Board of Health, appointed in 1872, serving one term. In 1866, Dr. Daniels spent several months attending lectures and visiting hospitals throughout the country. He was one of the directors of the First National Bank of St. Peter, a director of the city library and, in 1899, was appointed a member of the State Board of Hospital Trustees. In 1887 and 1888 he traveled abroad and, during the nineties, he often visited California, eventually moving there and remaining, in retirement, until his death at Pomona, February 17, 1923, at the age of ninety-four. He was a member of the Nicollet County Medical Society, the Minnesota Valley Medical Society, the Minnesota State and the American Medical Associations.

Daniels, Jared Waldo, the son of Dr. Asa W. Daniels, was born in St. Peter, in 1867. He attended school there, entered the University of Minnesota in 1887 and, later, Rush Medical College. He received his medical degree from Rush in 1889. In 1890 he also received a degree from Columbia University. At this time he began to practice in St. Peter. In 1893 and 1894 he took postgraduate work in London and returned to St. Peter, to resume practice. During World War I he was the first from Nicollet county to receive a commission. Since the war he has held a commission as major in the officers Reserve Corps. He was,

for many years, a member of the school board in St. Peter and coroner of Nicollet County. He was a member of the Minnesota Valley Medical Society and the Minnesota State Medical Association. He compiled the history of medical men and societies of Nicollet county in Gresham's *History of Nicollet and Le Sueur Counties* (1916).

Daniels, Jared Waldo, the brother of Dr. Asa W. Daniels, was born in Stratford, New Hampshire, June 15, 1827. He attended Lancaster Academy and Belleview Medical College. In 1855 he came to Minnesota and was appointed government physician at the Yellow Medicine Indian agency (the Upper Sioux agency). In 1860 he commenced practice in St. Peter, but left in October, 1861, when he was appointed physician in a military hospital in Washington. He was assistant surgeon of the Sixth Regiment, Minnesota Volunteer Infantry, from August, 1862, until December, 1863, and surgeon of the Second Minnesota Cavalry from January, 1864, until November, 1865, with the rank of major. He served in the Department of Minnesota under General H. H. Sibley in 1862 and 1863, in the Department of Missouri under General Alfred Sully in 1864, and again in the Department of Minnesota from the fall of 1864 until discharged. In 1865 he settled in Faribault, Rice County, and probably served there as an Indian agent. From 1867 until about 1882, he apparently resided, off and on, in St. Peter. From 1882 until 1900 he was in Faribault. In 1869 Dr. Daniels was appointed agent at the Sisseton Indian agency and, about a year later, was appointed to the Red Cloud agency in Wyoming. In 1873 he was made inspector of Indian agencies and, at intervals between that time and 1887, made treaties with the Sioux and was appointed to special commissions which treated with tribes in Dakota, Montana, Idaho and Washington. In 1900 he moved to Los Angeles, California, where he died May 3, 1904, after being ill for a short time with pneumonia. He was buried in the family lot at St. Peter.

Darling, W. H., was an assistant physician at the St. Peter Hospital for the Insane from September, 1895, until January, 1908. In the winter of 1897-98 he took postgraduate work in Boston and, in December, 1898, he took additional courses in New York. In May, 1898, he was chosen assistant superintendent of the hospital, succeeding Dr. G. A. Chilgren.

Erdman, C. A., came from Minneapolis to be temporary assistant at the state hospital at St. Peter from May to June, 1893.

Ewing, R. H., was one of the early physicians of St. Peter, locating there in 1856. He left for the south three years later. He died in Grand Rapids, Michigan, in the fall of 1876.

Everett, Ella B., was born in 1866. She was graduated from the Women's Medical College of Pennsylvania in 1891 and became superintendent of the Northwestern Hospital in Minneapolis. In September, 1893, she commenced work as assistant physician at the St. Peter hospital. In 1896 she went to Mankato to practice and a year later she returned to Philadelphia to take charge of a women's hospital. She served for several years on the faculty of her alma mater, until her death in 1934, following an automobile accident.

President's Letter

MENTAL HEALTH PROGRAM PROGRESSES

Treatment of the mentally ill has progressed mightily since the time when these unfortunates were thought to be possessed by evil spirits and when they were often burned as witches or punished as criminals.

Typical of the modern approach to this problem is the mental health bill passed by the Minnesota legislature this session. An outgrowth of long and continuing efforts by the medical profession and promising to correct many of the deficiencies of the state's present program, the bill still cannot be regarded as the final answer to the problem of mental health; nor will it result in an immediate, sharp decrease in the number of institutionalized mental patients.

Governor Youngdahl in a recent radio speech stated:

"Doctors expert in the field of psychiatry hold out the hope that with adequate funds and sufficient trained personnel our mental hospitals may be able in time to send home within six months as many as 75 per cent of the patients admitted.

"Whatever the percentage, it is clear that with the new services now made possible we will be able to restore many of the patients to health in a short time."

Basing my opinion on forty-two years in private practice of neuro-psychiatry, it seems to me unwise to be unduly optimistic, to expect such a high recovery rate. This will lead not only to great disappointment to both patients and relatives but perhaps to unjust criticism of state hospital superintendents, if this high goal is not attained under this new program.

The Governor's Advisory Council on Mental Health, which included seven psychiatrists, called attention to one factor that will continue to retard the number of cures affected: "At the present time 40 per cent of all patients admitted to the state mental hospitals are over sixty-five years of age. All available population statistics and expert opinion indicate that for the next thirty or forty years the percentage of people over sixty-five in the general population will continue to increase. It is evident that the care of the aged and senile will continue to be an increasing problem."

The 28-million-dollar program will, of course, make these and the other mental patients more comfortable and will facilitate the possibility of cure in many cases; but a certain percentage will remain incurable.

More adequate housing will be provided for the state's 15,000 men, women and children now suffering from mental ills and an increase of more than 20 per cent in the number of attendants, now listed at 1,900, will assure closer supervision and attention to the patients' needs. Again, following the recommendations of the advisory council, administrators of the program will seek for additional highly trained doctors, psychologists and occupational therapists. Research will be aided by an annual $50,000 grant.

This is a good beginning, but, as such, it must not be mistaken for the final chapter in Minnesota's attempt to help the mentally ill.

President, Minnesota State Medical Association

(Continued from Page 502)

Flint, Edwin N., was graduated from the University of Illinois in 1887. He practiced in Saint Paul and, in February, 1890, came to St. Peter, where he served at the state hospital as assistant physician. In 1893 he resigned this position and opened an office in St. Peter. After a few months he moved to Winthrop, Sibley County, where he was appointed pension surgeon in that district. He also practiced in Gaylord, in the same county, and finally located permanently in Chicago.

Flossian, M., was a French physician who located in St. Peter in June, 1864.

Foster, Thomas R., was an assistant physician at the St. Peter Hospital for the Insane from October, 1893, to May, 1895, when he left for Kankakee, Illinois. He served a second term at the hospital from September, 1920, to June, 1921.

Hasson, Alexander, was born in Maryland and received his appointment in the army from that state. He became an assistant surgeon June 29, 1849, and, August 17, 1861, became a surgeon, with the rank of major. March 13, 1865, he was made brevet lieutenant colonel for faithful and meritorious service during the war. He was the first physician in Nicollet County, serving as post surgeon at Fort Ridgely for a few months in 1852. He died in March, 1877.

Hoberg, C., located at Traverse in 1864, where he practiced until his death, June 19, 1874.

Horne, ———, came to St. Peter in 1856 or 1857. He superintended the building of the first school in St. Peter. In a few years he moved to New England and died at his home in Malden, Massachusetts, in the spring of 1899.

Humphrey, Philander P., located in St. Peter in June, 1857, and practiced there until appointed physician at the Lower Sioux agency in Redwood county. In the Indian outbreak of 1862 he and his family escaped from the agency and made their way toward Fort Ridgely. They managed to cross the river and, on the other side, entered a house to rest. The eldest boy was sent to the spring to get some water for his mother who was not well. While he was gone Dr. Humphrey, his wife and the other children were murdered by the Indians.

Hunter, William F., came to St. Peter in the spring of 1855. He practiced there only a few years.

James, John Henry, was assistant physician at the St. Peter Hospital from 1876 until 1891 when he moved to Mankato. While at the hospital he was often called to attend patients in St. Peter and the surrounding country and he performed several difficult operations of the eye.

THE ANTICOAGULANTS

THE ANTICOAGULANTS, dicumarol and heparin, have proven of great value in a variety of conditions in which prevention of the formation or extension of an intravascular thrombus is indicated. When prompt action is desired, intravenous heparin is indicated. Its cost, however, has limited its use. Dicumarol, when given orally in the usual doses, does not become effective for two or three days in most cases. The importance of prothrombin determinations before the administration of either anticoagulant and the frequent repetition of the test while it is being administered cannot be too strongly emphasized. Some patients, normally or as a result of their illness, have an already low prothrombin, and the response to this medication is variable. Unless, too, a reliable laboratory is available, the anticoagulant should not be used. Considerable confusion has resulted from the fact that various methods have been used by the laboratories in reporting the prothrombin test, and the clinician must be familiar with the method used.

The value of the anticoagulants, more particularly discumarol, in coronary thrombosis has been well established. While many patients do well without dicumarol, reports of a large series indicate a lowering in thrombo-embolic complications and, according to more recent reports, in mortality from its use. The occasional evidence of an extension of the coronary thrombotic process suggests the advisability of the immediate intravenous administration of heparin. However, in the great majority of cases, the thrombotic process in the coronary vessel is complete before the patient is seen and a prothrombin determination can be made. As most thrombo-embolic complications arise from four to twenty days following the attack, dicumarol is well suited but should be continued for a period of four weeks. There is good reason to expect less chance for the formation of intracardiac thrombi and consequent peripheral emboli by the lowering of the coagulability of the blood.

In the presence of phlebothrombosis, and particularly when the process is extending or recurrent, the anticoagulants are of value. For thromboangiitis obliterns or severe arteriosclerosis with evidence of thrombosis formation, they may be used. Some favorable results have been reported in pulling a patient through an acute phase.

The use of the anticoagulants in the treatment of an arterial embolus in the expectation of limiting thrombosis formation is logical. Fifty milligrams of heparin should be given intravenously immediately, as well as the usual oral doses of dicumarol and papavarin, grain ½, intravenously, to counteract the arterial spasm in the collateral arteries which causes extension of the thrombotic process. Incidentally, in this condition the head of the bed should be elevated and not the extremity involved, no heat should be applied and the patient should be given whiskey for its dilation effect on the arteries. This routine is likely to prove more effective than an attempt at embolectomy.

An additional warning should be given that the use of dicumarol is contraindicated in the presence of kidney or hepatic disease, purpura of any type, any bleeding tendency, in the presence of subacute bacterial endocarditis, or after operations on the brain or spinal cord. It should be used with caution in the presence of an acute peptic ulcer or open wounds.

MEDICAL PUBLICITY

WITH the decision of the House of Delegates of the American Medical Association last December to undertake a national education campaign, the question has arisen in the minds of many members as to what their attitude should be to the National Physicians Committee. This question has been solved by action of the Trustees of the National Physicians Committee at its meeting April 10, 1949, which approved the action of its Managing Committee authorizing cessation of all activities of the organization as of April 1, 1949, and liquidating the affairs of the committee.

The National Physicians Committee was formed ten years ago by a group of officers and fellows of the AMA to carry on medical publicity as an independent organization. Its activities were supported by voluntary contributions by physicians and other individuals and organizations interested in extending medical service without sacrificing the private practice of medicine. Under the able leadership of Dr. Edward H. Cary, chairman of the committee, and John Pratt, executive secretary, the committee has carried on a dynamic program and deserves the thanks of the medical profession and the public at large. In taking a vigorous stand against socialism and communism in general, it has aroused the bitter enmity of the proponents of a change in our social order.

Whether the repercussions which followed the transmissal of Dan Gilbert's Washington Letter of December, 1948, to the medical profession and the protestant clergy of the country had anything to do with the termination of the NPC, we do not know. That these repercussions were widespread and violent is evident. It would seem that it was not so much the material contained in the letter as the author and his former association with the Silver Shirts that aroused such a furor. According to newspaper comment, repercussions have had their effect on members of the medical profession and may have accounted for the reversal of the vote of the membership of the New York County Medical Society on the twenty-five dollar AMA assessment in January. The majority of the membership were in favor of the assessment. In a recent vote, the majority of those voting were opposed. The count showed 432 against the assessment and 333 for it. The total membership, however, is nearly 6,000.

According to an editorial which appeared in the February 26, 1949, number of the *Journal* AMA many hundreds of letters have been received by the AMA office bitterly condemning the Dan Gilbert letter. The editorial explains: "The Gilbert letter was sent without the knowledge of any official of the AMA; every official of the AMA joins in condemning the letter as an expression of medical opinion in this country and the AMA does not require allies of doubtful repute in its campaign for the maintenance of a high quality of medical care and for freedom in medicine in our country."

It would perhaps be too much to expect 100 per cent of the AMA membership to back any policy proposed by the House of Delegates. If there is any activity of the AMA, however, which deserves 100 per cent support it is the National Publicity Campaign adopted by the House of Delegates last December in St. Louis. There can be no doubt that the great majority of the profession realize the necessity of a vigorous publicity campaign to acquaint the public with the importance of preserving the private practice of medicine and the extension of voluntary insurance to provide for the cost of hospital and medical care, rather than to place medical care under bureaucratic control by means of compulsory government taxation. The funds raised by the twenty-five dollar assessment will be used in large part for this publicity. It is not being used for a lobby in Washington, and this repeated accusation has been denied from the start.

The protest against the present attitudes and policies of the AMA in regard to the problem of medical care with the list of signees of the protest was published in the *Journal* AMA, February 19, 1949 (page 532). The reply by the officers and trustees of the Association also appears. A careful reading of the protest and reply indicate that the signers were not acquainted with the purpose of the assessment or the program of the AMA for the advancement of medicine and public health. At a time when it is essential that the medical profession present a united front in opposition to the proponents of complete socialization of the practice of medicine, this protest is most unfortunate.

The program of the AMA for the advancement of medicine and public health† does not consist entirely of opposition to bureaucratic administration of medical care as typified by the Wagner-Murray-Dingell Bill. It contains positive objectives which have been approved by the House of Delegates of the AMA.

†See pages 477-478 this issue.

RELATIVE VALUES

THE total number of persons now covered by all voluntary agencies is 55,000,000 for hospitalization and 37,000,000 for surgical or medical care. Of these, over 30,000,000 people are covered by Blue Cross type hospital insurance and over 10,000,000 by Blue Shield type medical care in-

(Continued on Page 509)

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

TRUMAN OPEN TO HEALTH COMPROMISE

President Truman has indicated that he will settle for less in the matter of national health programs.

In heralding the introduction of the Administration bill for compulsory health insurance, Mr. Truman was less specific than he had been a year ago when he was quoting costs and benefits. This time he said nothing about how the new plan would be financed, admitting only that it would be "costly," and hastily qualifying that statement with the assertion that the program would actually save more than it cost.

Truman Defensive

The chief executive was apparently on the defensive about his health scheme, for his statement was concerned largely with attempts to refute the charges that such a tax-paid, government-supervised program would result in socialization, soaring costs and lowered quality of medical care.

He protested that the United States plan would not be modeled after the British plan, that it would not entail a multiplicity of federal employes, that it would not deny patients the right of selecting their own doctors and hospitals, nor would it make doctors employes of the government.

More for Same Money

What it would do, he asserts, is get more care for the same amount of money (four per cent of the national income) that is now being spent for health.

To strengthen his argument that the rank and file of American citizens are unprepared for medical emergencies, Mr. Truman quoted a figure of 3,500,000 as representing the number of people having insurance which provides adequate health protection.

In a statement released for publication April 25, Dr. Elmer Henderson, chairman of the AMA Board of Trustees, said:

"Ten or fifteen years ago that was true. Today, Mr. President, 55,000,000 Americans are protected, under the voluntary health insurance systems of this country, against the costs of hospital care, and 37,000,000 policyholders are insured against surgical or medical bills.

More for Less Money

"Again, the President falls into the error of stating that only limited, inadequate health protection is available under the voluntary health insurance systems. Actually, the voluntary systems are providing better coverage today than any compulsory program yet proposed—at about half the price.

"President Truman also makes the amazing assertion that adequate medical care is now beyond the means of all but the upper income groups. On the contrary, any family which can afford a package of cigarettes a day, or a weekly movie, can afford the finest kind of pre-paid medical and hospital protection. The cost is about the same."

Sponsors of the legislation introduced it in the house and senate April 25. One of them, Senator Humphrey, was quoted as saying, "This is actually an economy program—probably the greatest economy program the government ever launched."

Congress Too Busy

Laudatory as they are about the bill, neither the sponsors nor President Truman indicate optimism about it passing this session. Congress, absorbed with other changes in the social security laws, a new farm program, military aid for Europe and ratification of the Atlantic pact, has exhibited little more than an academic interest in the proposal. Washington observers look for the real showdown this fall or next year.

In the meantime, the program has suffered some severe setbacks.

While President Truman was carefully timing

his oratory of transmittal to Congress, a number of groups were loosing counter-blasts:

*The same day, Daughters of the American Revolution adopted a strong resolution opposing Wagner-Murray-Dingell legislation.

*Senator Taft predicted that Truman's recommendation of "socialized medicine" would be emphatically rejected by Congress.

*Three important Catholic organizations: Bureau of Health and Hospitals of the National Catholic Welfare Conference, National Conference of Catholic Charities, and Catholic Hospital Association, issued a 20-page statement denouncing the national health insurance program and favoring, instead, a comprehensive voluntary plan along the lines of the Taft-Smith-Donnell Bill, S.1581.

Public Knows Socialism

In addition, the proponents of national health taxation, are becoming aware that the words "socialized medicine" are becoming inseparably linked with the plan.

Their only escape from this unpleasantly true label seems to be an attempt to apply it to other health proposals now pending in Congress. Senator Murray, on an NBC network broadcast April 22, attacked the Taft-Smith-Donnell Bill as a step toward "Soviet regimented medicine," amplifying what he had said a week before when the measure was introduced.

The American people are apprehensive about any plan that resembles regimentation, socialism or communism, and they will not endorse national compulsory health insurance as long as the same sales talk applies equally to compulsory health insurance and socialized medicine.

"Insurance" Misleading

Furthermore, the term "insurance" in connection with the compulsory health plan is being seen now in its true light, that of a misleading facade.

As the *Minneapolis Tribune* pointed out, editorially, April 23: "What Mr. Truman proposes, however, is not insurance at all . . . Insurance, as Senator Taft pointed out . . . is a free act by which a man agrees to pay a definite sum to receive protection or benefits worth approximately what he pays.

"If a man is compelled to pay something to the government he has to accept what the government gives him, or fails to give him."

MSMA HOLDS FIRST PRESS CONFERENCE

The first state-wide Medical Press Conference of the Minnesota State Medical Association has been established, by popular acclaim, as an annual event.

Held April 8, at the Hotel Radisson, the meeting drew nearly three hundred and fifty doctors and editors from all parts of the state. Announcements of the meeting had been heralded with great editorial interest, indicating that newspapermen were acutely aware of the need for better understanding between the two professions.

One newspaper, *The Montevideo News*, declared unhesitatingly, "Here is a sign of progress toward better public understanding, all around. The medical men and women have a great and good story to tell and to sell, but they have been incredibly backward in doing it."

"Too Many Misunderstandings"

This backwardness was admitted by Dr. E. M. Hammes, president of the MSMA, as he opened the afternoon discussion session by saying, "There have been far too many misunderstandings between us . . . on matters of news coverage and ethics, especially."

Dr. Hammes added that the question of socialized medicine is "of like concern to doctors and to editors and reporters, whose civic responsibilities certainly include the health level of their communities."

Citing the multiple-threat of socialized medicine, Dr. Hammes made clear the position of Minnesota doctors: "We're not asking you to fight our battle, but only to continue your own battle for freedom, so that our country will not fall prey to socialistic slavery."

The meeting was then signed over to the newspapermen and women to develop as they wished. Interesting discussions on a variety of problems relating to journalism and medicine and, consequently, to the public at large, resulted.

Russia Mid-Victorian

A 6:30 banquet was followed by two addresses: Irving Pflaum, foreign editor of the *Chicago Sun-Times*, relating his observations in Russia, referred to the iron curtain as a device for keeping Russians in, not for keeping others out of the country. He described Russia as mid-Victorian in its present living conditions and cited

the extreme poverty and hardships that exist there now.

John Bach, press relations director for the American Medical Association, analyzed the Ewing report in his talk entitled "Pick-Pocket Medicine," contrasting the advances in medical science under a system of private enterprise and the conditions that exist, medically speaking, in the countries where socialized medicine holds sway.

High point of the meeting for many who attended was the unscheduled appearance of Dr. Mitrofan Smorszczok, displaced physician from Russian-controlled Poland. Describing Communism as "a permanent crime against humanity," Dr. Smorszczok delineated his own experiences as a physician forced to take orders from the government.

More Smorszczok's Wanted

Editorial comment on Dr. Smorszczok was generally in line with what the *Ivanhoe Times* said: "As Dr. Smorszczok told briefly of his experiences under the Soviet thumb, we wished desperately that more parlor pinks in this free country of ours would abandon their pride in intellectual liberalism just long enough to give Dr. Smorszczok's message a fair hearing. We wished desperately that where there is but one Dr. Smorszczok and several Elmer Benson's and Henry Wallace's that somehow we could reverse the ratio."

Speaking for the Minnesota Editorial association about the Press Conference as a whole President Alan C. McIntosh of Luverne, wrote:

"Minnesota medical men have led in so many fields . . . I think that this Medical Press Conference will blaze a new trail toward better public relations. We enjoyed the hospitality extended . . . we appreciated the opportunity to learn more about your problems . . ."

Because an industrial environment is supposed to be dirty, grimy, and dusty, it has, out of ignorance, been accused of being an incubator for tuberculosis. Such thinking disregards vital components outside of the working environment of the employe, such as the economic factor, living conditions, congested housing, improper nutrition, financial insecurity with all its attendant worry, personal and community hygiene.—Rutherford T. Johnstone, M.D., *American Review of Tuberculosis,* October, 1948.

St. Paul 2, Minnesota

Minneapolis Beauty Shop Owner Pleads Guilty to Abortion

Re: State of Minnesota vs. Louis Stanley Jensen.

On April 7, 1949, Louis Stanley Jensen, fifty-three years of age, 1707 Stevens Avenue, Minneapolis, was sentenced by the Hon. John A. Weeks, Judge of the District Court, to a term of not to exceed four years in the State Prison at Stillwater, following the defendant's plea of guilty on March 17, 1949, to an information charging him with the crime of abortion. Judge Weeks stayed the sentence and placed the defendant on probation for three years. Jensen operates the Jensen Salon of Beauty on the ground floor of the Foshay Tower Building, Minneapolis.

Jensen was arrested on March 15, 1949, following a complaint to the Minnesota State Board of Medical Examiners on February 28, 1949, that he was engaged in performing abortions. While the matter was under investigation, a similar complaint in another case was made to the office of Mr. Michael J. Dillon, County Attorney of Hennepin County. Accordingly, on March 15, Jensen was arrested and a complaint filed on March 16, charging him with the crime of abortion performed on a twenty-one-year-old unmarried St. Louis Park girl. On March 17, Jensen entered a plea of guilty in the District Court of Hennepin County. Jensen admitted that he had performed five or six abortions during the past five years. Jensen injected an alum solution into the uterus to bring about the abortion. The defendant stated that he made no charge for his services, and the evidence indicated that his statement was correct in that regard. Jensen stated to the Court that he was born in Albert Lea, Minnesota, and attended grade school in Minneapolis.

RELATIVE VALUES

(Continued from Page 506)

surance. The medical and surgical care coverage is growing by leaps and bounds, even faster than was the experience of the Blue Cross. These facts should be a potent argument against adoption of a compulsory government-supplied medical care and the scrapping of all the hospital and medical insurance policies now in effect.

When one considers that both a hospital and medical care policy can be obtained for the price of a package of cigarettes a day or a movie a week for the family, arguments as to the inability of the public to pay for the cost of sickness seem rather ridiculous.

Minnesota Academy of Medicine

Meeting of January 12, 1949

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 12, 1949. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the President, Dr. T. A. Peppard.

There were sixty-one members and one visitor present.

This being the Annual Presidents' Dinner, no business was transacted.

Dr. S. E. Sweitzer, as chairman of the meeting, introduced the Past Presidents who were present. These were: Drs. Ulrich, Hynes, LaVake, Jones, Drake, Johnson, Wilcox, Nordland, Zimmermann, Schulze, Hammes, and Peppard—retiring president. Dr. Lepak, president for 1949, was also introduced. The past president responded briefly.

MISTAKES IN DIAGNOSIS

T. A. PEPPARD, M.D.
Minneapolis, Minnesota

Dr. Peppard, Minneapolis, gave his address as retiring president. Lantern slides of charts were shown.

Abstract

The belief that mistakes carry real teaching value led me to review and analyze the records, selected from my files quite at random, of 100 patients who had come to autopsy. There were fifty-seven males and forty-three females seen from 1916 to 1944. Their ages ranged from eleven to ninety-two years: 20 per cent in each of the fifth, sixth, seventh and eighth decades. Approximately half of the patients were seen by one or more physicians other than myself.

Chart 1 illustrates the manner of arrangement used in summarizing each of the records. The clinical findings as they appeared in writing only were listed on the left and on the right was a corresponding list of the findings as determined by the pathologist. Whenever any question whatever arose, an error was charged so that bias could and would not favorably influence the results. In the illustrated case the provisional diagnosis of atypical pneumonia (though qualified) constituted an error and that of pulmonary infarction was counted as correct though qualified. The autopsy findings showed that there was cardiac hypertrophy, the heart weight being 400 grams, pulmonary edema, and moderate benign prostatic hypertrophy. In regard to the first, I had considered the percussion borders of the heart's dullness to be normal for this patient who was of broad habitus and the roentgen examination had showed findings reported as indicating the heart to be normal in size, shape and position. The second, pulmonary edema, was unquestionably a terminal event; and the third, prostatic hypertrophy, had been missed because no rectal examination had been made in this patient dying of coronary artery occlusion and myocardial infarction. Years before such examination had recorded normal findings and now no symptoms gave evidence of any abnormality. In this record then

STO - MALE - age 54

CLINICAL	AUTOPSY
1. Arteriosclerosis	1. Arteriosclerosis of Aorta
2. Coronary Artery Sclerosis	2. Coronary Artery Sclerosis
3. Coronary Artery Thrombosis	3. Coronary Artery Thrombosis - Rt. & Left
4. Myocardial Infarction	4. Myocardial Infarction
5. Congestive Heart Failure	5. Congestive Heart Failure
6. Atypical Pneumonia or Pulmonary Infarction	6. Pulmonary Infarction
7. Pulmonary Congestion	7. Pulmonary Congestion
8. Congestion of Liver	8. Congestion of Liver
9. Hernia (Rt. Inguinal)	9. Hernia (Rt. Inguinal)
	10. Cardiac Hypertrophy (400 gm)
	11. Pulmonary Edema
	12. Benign Prostatic Hypertrophy

Chart 1.

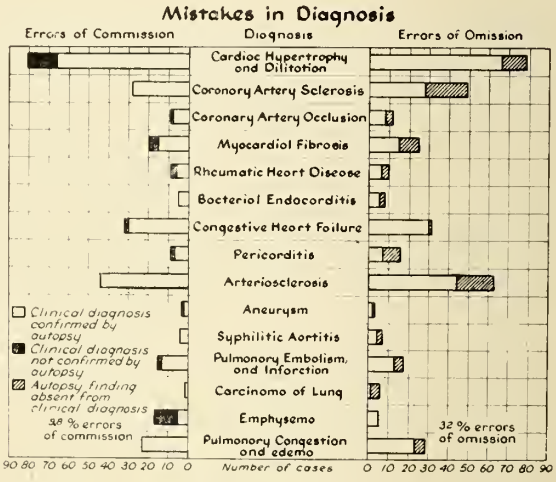

Chart 2.

there appear nine correct clinical diognoses, one of which was qualified and one erroneous diagnosis (also qualified). In the pathological study, there were likewise nine correct diagnoses and three findings that had been neglected.

After thus reviewing the entire 100 records, charts were prepared showing on the left errors of commission, and on the right errors of omission. The graph is in error in that fifteen mistakes of commission are shown in regard to cardiac hypertrophy and dilatation, when, in fact, the correct number was thirteen. Not shown on the chart, but included in the total figures, were thirty-five correct diagnoses of various conditions; three errors of commission and twenty errors of omission. The complete summary shows, among a total of 614 items: errors of omission 32 per cent; errors of commission 9.8 per cent.

Any possible value of this review lies in the discovery of reasons (never excuses) for the errors. Scrutiny of each mistake has led me to classify them as shown in Chart 4. Naturally there is some, even much, overlapping in the various divisions. The faculty of judgment will always be a variable factor in various individuals and no doubt will vary in the same person from time to time according to his training, experience, and breadth and depth of wisdom. If evidence is sought and not found, and if our examinations are incomplete, even if some legitimate reason exists for our inability to ascertain the fact, our concept must necessarily be incomplete and errors will be inevitable.

Those in division 5 (12.5 per cent), those in division 4 (8.9 per cent), and those in sub-group 2 (lack of re-examination) in division 3 (5.3 per cent), or something over a fourth (26.7 per cent) of the errors, with care and diligence can readily be obviated.

"He who has never erred in his diagnosis has not really practised medicine."

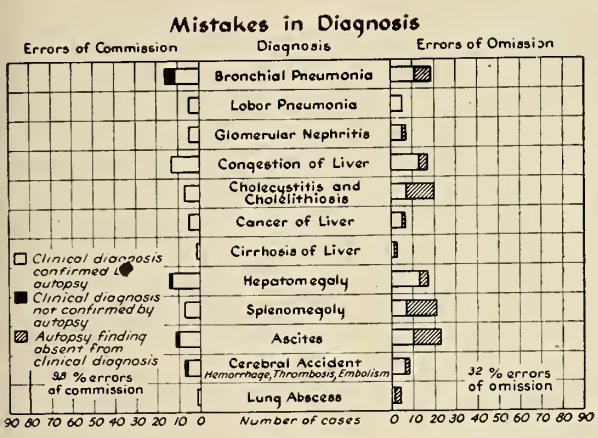

Chart 3.

MISTAKES IN DIAGNOSIS

1. Error in Judgment - including all those listed as errors of commission; misinterpretation of signs		28.5%
2. No Evidence - Symptoms and / or signs not obtained		29.2%
3. Examination - Examination incomplete; nothing to suggest that some special procedure be undertaken; patient's condition preventing some particular examination	10%)	
Lack of Re-examination	5.3%)	
Death occurring within 24 hours or less - patisnt's condition prevsnting proper thorough examination	5.3%)	20.6%
4. Diverted Attention - Some lesion of such prominence (usually that causing death) that little or no attention was given anything else - not following through even though thsre was some suggestive evidence		8.9%
5. Gross Error in Recording Diagnosis	4.2%)	
Neglecting the obvious	8.2%)	12.5%

Chart 4.

Discussion

Dr. H. L. Ulrich, Minneapolis: This is an extremely interesting paper and also is a labor of love. Dr. Peppard is a meticulous diagnostician and I want to thank him for presenting it this evening. I am glad he mentioned Dr. Robert Robertson's (deceased) paper on autohypnosis in diagnosis. This failing is prevalent in all of us, particularly the surgeons.

It takes courage to call attention to our mistakes as measured by the postmortem yardstick. We can console ourselves with the knowledge that even the pathologist at times is bewildered. I want to congratulate Dr. Peppard for his excellent presentation.

The meeting was adjourned.

A. E. Cardle, *Secretary*

TIME TO STAND UP AND BE COUNTED!

There have been a few instances recently in which medical organizations, particularly scientific groups, have indicated reluctance to go on record against Compulsory Health Insurance on the ground of propriety.

The question raised is whether a scientific group should "get mixed up in politics."

The answer to that question is that we *are* "mixed up in politics" whether we like it or not, because medicine has been brought under political attack.

The only question which remains is whether we are going to defend our profession against that political attack—and how we can do it most effectively.

If Compulsory Health Insurance is enacted, every medical organization will be subject to political controls and influence—and every doctor will be restricted in the practice of his profession. Then we really will be "mixed up in politics"!

That issue, we believe, makes it imperative that all medical organizations—scientific or otherwise—take their stand, publicly and vigorously, against the emasculation of sound medical practice.

American medicine needs to present a united front against politically controlled medical practice—and we believe it is not only ethical, but highly desirable for our scientific groups to make their position known.

Let's stand up and be counted!

—George F. Lull, M.D., General Manager

✦ Reports and Announcements ✦

INTERNATIONAL ACADEMY OF PROCTOLOGY

The first meeting of the newly formed International Academy of Proctology will be held at the Marlborough-Blenheim in Atlantic City, N. J., on Friday, June 10, 1949.

The scientific portion of the program will consist of the presentation of papers and motion picture films of interest to all physicians as well as to those specializing in Proctology.

Further information and a copy of the program may be obtained by writing to Dr. Alfred J. Cantor, International Academy of Proctology, 43-55 Kissena Blvd., Flushing, N. Y.

$250,000 GIVEN FOR RESEARCH BY AMERICAN HEART ASSOCIATION

Research awards totaling $250,000 have been allocated by the American Heart Association to twenty-six investigators and six medical schools and hospitals for studies in heart and circulatory disease, it was announced today by Mr. A. W. Robertson, Chairman, of the Board.

The awards include two to established investigators engaged in independent research, twenty-four research fellowships to younger scientists, six grants-in-aid to institutions, and provide additional funds for basic research and co-operative research studies. Selection of individuals and of projects to receive grants was made by the Research Committee of the American Heart Association's Scientific Council, of which Arlie R. Barnes, M.D., of Rochester, Minnesota, is Chairman. Louis N. Katz, M.D., Chicago, headed the research committee.

Policy considerations governing the allocations included the support of younger scientists in the medical research field to develop investigators in cardiovascular disease. To this end, $103,800 was allocated to 25 research fellowships, the individual stipends ranging from $3,000 to $4,000 to cover one-year periods beginning, in most cases, on July 1, 1949.

CONFERENCE OF PRESIDENTS AND OTHER OFFICERS OF STATE MEDICAL ASSOCIATIONS

This valuable conference of presidents and other officers of State Medical Associations will again be held the Sunday afternoon preceding the opening of the general session of the American Medical Association and will be open to all physicians. This year the meeting will be held Sunday afternoon, June 5, 1949, in the Rose Room of the Traymore Hotel in Atlantic City.

Among the speakers will be:

Cecil Palmer, English publisher, author and journalist, will tell of the impact of socialized medicine on the British doctor and his patients.

W. Allan Richardson, editor of *Medical Economics,* who is now in England, will present an American viewpoint of the British health system.

Edward H. O'Connor, managing director of the Insurance Economics Society of America, will discuss legislation relative to compulsory disability compensation programs now operating in three states.

Dr. Bert G. Thomas of California will speak on the medical implications of cash sickness compensation acts.

Dr. Clarence Northcutt, president of the Oklahoma State Medical Association, and *Dr. George F. Lull,* secretary of the AMA, will also address the conference on medical organizations.

NATIONAL CONFERENCE OF COUNTY MEDICAL SOCIETY OFFICERS

The fifth National Conference of County Medical Society Officers will be held in the morning and evening of Sunday, June 5, 1949, in the Rose Room of the Traymore Hotel, Atlantic City.

The morning program will include the presentation of emergency call plans with discussion. In the evening Mr. Clem Whitaker, Director of the AMA National Education Campaign, will speak, and Senator John L. McClellan of Arkansas will discuss health problems.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

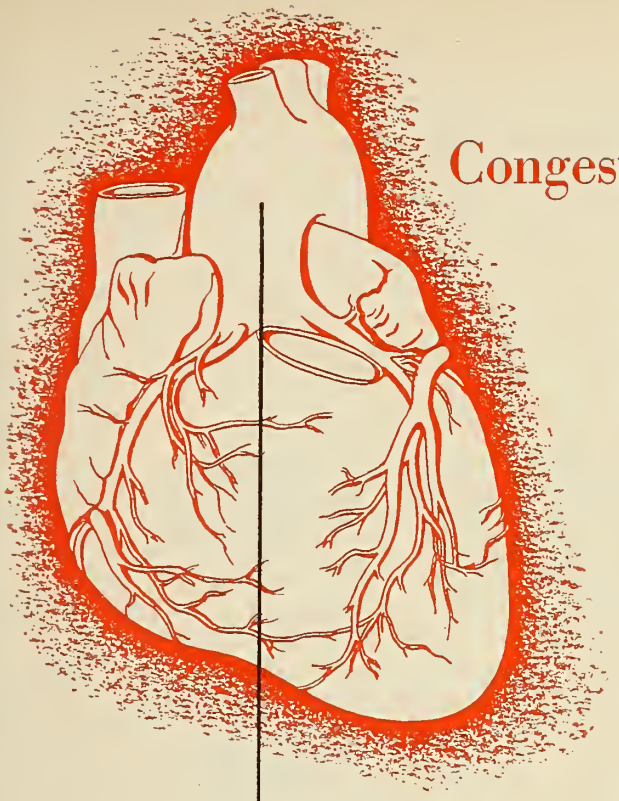
The Minnesota Society of Neurology and Psychiatry met in Rochester on May 14 at St. Mary's Hospital for surgical clinics and later at the Medical Little Theater for a clinico-pathologic conference and the following addresses:

"Neurologic Evaluation of the Cutaneous Histamine Reaction." By Dr. I. S. Cooper.

"Intramedullary Cord Tumors." By Dr. H. W. Woltman and Dr. J. W. Kernohan.

"Preventive Psychiatry in the Rochester Child Health Institute." By Dr. B. M. Spock.

Dr. O. H. Beahrs entertained luncheon guests with prestidigitation.



Dr. W. McK. Craig is president, and Dr. Royal C. Gray, secretary-treasurer of the Society.

E. T. BELL TO BE HONORED

On June 15, 1949, Dr. E. T. Bell, Professor of Pathology, reaches the age of retirement and will relinquish the chair. He has served the University since 1910, first teaching in Anatomy, and from 1911 until the present time in the Department of Pathology. He was appointed head of the department in 1921 and in this capacity has directed its activities in the intervening years. Everyone who has had any contact with medicine in the Northwest knows how profound his influence has been, not alone on teaching and research in pathology, but on the practice of medicine, as a whole.

Many physicians and former students have brought to the Minnesota Medical Foundation the request that

In Memoriam

THOMAS NELSON DUNCAN

Dr. T. N. Duncan, a practitioner at Bigfork, Minnesota, for nearly forty years, passed away March 16, 1949, at the age of seventy-one.

Thomas Nelson Duncan was born in Delavan, Illinois, September 14, 1877. He received his college education at Kansas State University and his M.D. degree from the St. Louis College of Medicine.

On July 25, 1908, Dr. Duncan was united in marriage to Inice Esson of Lawrence, Kansas. They were blessed with eleven children, nine of whom survive. Mrs. Duncan also is living.

Dr. Duncan was a pioneer of the Bigfork country for many years, having been the only doctor for miles around. He served his patients by horseback and boat in summer and by dog sled or on foot in the winter.

WILLIAM A. PLUMMER

Dr. William A. Plummer, sixty-five years old, a member of the staff of the Mayo Clinic for almost forty years, died of a heart attack at his home on March 22, 1949.

Dr. Plummer, younger brother of the late Dr. Henry Plummer, came to the Mayo Clinic in June, 1910, after his graduation from the Northwestern University Medical School.

A year later, on Aug. 29, 1911, he was married to Corena Popple, who survives him. On Feb. 1, 1917, Dr. Plummer became head of a section of medicine at the Clinic, a position he held until October, 1947, when he became a senior consultant in medicine.

He was an associate professor of medicine in the Mayo Foundation, graduate school of the University of Minnesota.

William A. Plummer was born at Racine, Wisconsin, June 30, 1883. Both his father and grandfather were physicians. His father, Dr. Albert Plummer, was well known in southeastern Minnesota.

Dr. Plummer entered Northwestern University after his graduation from Stewartville High School.

During his career he was the author of approximately forty papers in medical journals. In 1937 he was specified as a specialist in internal medicine by the American Board of Internal Medicine. His specialty was diseases of the thyroid gland.

Dr. Plummer was a fellow in both the American Medical Association and the American College of Physicians.

Other scientific groups he belonged to were the Minnesota Society of Internal Medicine, Southern Minnesota Medical Association, American Goiter Association, Central Society for Clinical Research, Alumni Association of Mayo Foundation, Association for the Study of Internal Secretions, Central Interurban Clinical club, Minnesota State Medical Association, Olmsted-Houston-Fillmore Dodge County Medical Society and Sigma Xi.

Until recently, Dr. Plummer owned a farm, where he spent much of his time.

Besides his wife, one daughter, Mrs. Blair Stark of Heywood, Calif., and two sons, John Henry Plummer of Pomona, N. Y., and William Plummer of Hollywood, Calif., survive him.

REPORTS AND ANNOUNCEMENTS

E. T. BELL TO BE HONORED

(Continued from Page 542)

a fund be established in Dr. Bell's honor, to perpetuate in some measure his influence as a teacher, investigator, and consultant.

As a result of these requests, an advisory committee was appointed and has recommended the establishment of a fund of $100,000 to create and maintain for teaching and research a Museum of Pathology in the Medical School, which will bear his name.

The Sponsoring Committee feels confident that there will be a gratifying response to requests to his many friends and admirers for subscriptions to this fund. It has been suggested that contributions might range from $100 to $1,000 or higher in individual instances.

This is a splendid opportunity to promote teaching and research in pathology and to honor a great leader in medicine.

It should be added that as a special project of the Greater University Fund any donor to the E. T. Bell Fund of the Minnesota Medical Foundation will also be listed and recognized as a donor to the Greater University Fund, even though his gift is entirely to the Bell Fund.

Dr. James McCartney is chairman of the E. T. Bell Fund Committee. Appropriate forms will be furnished by the Minnesota Medical Foundation, 132 Medical Sciences Building, University Campus, Minneapolis, to physicians and other friends of Dr. Bell for use in supporting the E. T. Bell Fund.

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held its regular monthly meeting in Stillwater on April 12. Guest speaker at the meeting was Dr. Richard L. Varco, associate professor of surgery at the University of Minnesota Medical School, who presented a talk on "Cancer of the Lung," illustrating his discussion with lantern slides.

Woman's Auxiliary

WORLD MEDICS FIND GENERAL AGREEMENT

Mrs. H. F. Wahlquist

The World Medical Association, including representatives of forty nations, finds languages about the only block to complete agreement, according to Dr. Louis Bauer, vice chairman of the AMA Board of Trustees and secretary-general of the World Medical Association.

Dr. Bauer, addressing a recent meeting of the National Medical Auxiliary, noted the "surprising unanimity" which characterizes meetings of the WMA. Several significant actions were taken at the September, 1948, meeting of the organization, in Geneva, among them the revision of the Hippocratic Oath to read:

"Now being admitted to the profession of medicine, I solemnly pledge to consecrate my life to the service of humanity. I will give respect and gratitude to my deserving teachers. I will practice medicine with conscience and dignity. The health and life of my patient will be my first consideration. I will hold in confidence all that my patient confides in me. I will maintain the honor and the noble traditions of the medical profession. My colleagues will be my brothers. I will not permit considerations of race, religion, nationality, party politics or social standing to intervene between my duty and my patient. I will maintain the utmost respect for human life from the time of its conception. Even under threat I will not use my knowledge contrary to the laws of humanity. These promises I make freely and upon my honor."

At present German doctors are not considered in good standing because they have not decried the action of their associates. Not until they take action to punish those physicians responsible for war crimes will they be accepted in the World Medical Association. The Czechoslovakian delegation was compelled to withdraw because of the abolishment of its medical association by the communistic government (each country's medical association has two delegates).

Delegates found common ground in their distaste for socialized medicine, Dr. Bauer pointed out. Those who represented countries where socialized medicine is in effect wanted to do everything in their power to keep the situation from becoming worse.

The objectives of the WMA are well defined: first, it acts as a liaison for doctors and medical associations the world over, and is useful in disseminating information; it helps to promote peace, by furthering international relationships; and, of prime importance is the association's attempt to raise the standards of medicine and the health of the people of the world.

Dr. Bauer urged the Auxiliary members to interest physicians and lay persons in becoming members of a committee, which has been formed in the United States, to raise funds for the WMA. For information, they were referred to: World Medical Association, 2 East 103rd street, New York, 29, New York.

AUXILIARY AIDS CANCER HOME

Mrs. Charles W. Waas

Among the cancer aid activities of the Auxiliary to the Minnesota State Medical Association is helping with funds and dressings, for the Lady of Good Counsel Cancer Home in Saint Paul.

Opened in Saint Paul, in 1941, on the corner of St. Anthony and Cleveland avenues, the hospital is one of six of its kind in the United States. The first was started in New York City in 1896 by Rose Hawthorne Lathrop, daughter of the distinguished American novelist, Nathaniel Hawthorne. Mrs. Lathrop devoted her life to easing the suffering of incurable cancer victims who were living in New York slums.

The work grew and Mrs. Lathrop and the women who became associated with her banded together, under the name of Servants of Relief, as Sisters of the Third Order of St. Dominic for the exclusive care of indigent patients incurably ill of cancer. Since that time, contributions from sympathetic persons throughout the United States have enabled the Sisters to operate hospitals in six cities.
